At the general meeting of the shareholders of this Company held at the offices, Old Broad-street, **Mr. Charles W. Parish**, who presided, stated that the results shown in the revenue account for the half-year ended Dec. 31 last were not by any means of that excellent character to which they had been accustomed. It was disappointing to see their traffic receipts falling off so seriously, but the competition of new routes and the reduction of rates had naturally upset the unique position which the Company held for many years, and now the Board would have to work hard in order to meet the change of circumstances. Nothing that the Company could have done would have altered the march of historical progress in connection with the island of Cuba. The United States and Cuba were now negotiating as to the future status and government of the island, and some persons believed that with the end of Spanish rule there would be a rapid outburst of prosperous business, but that was scarcely reasonable, and both the United States and Cuba would require a full measure of patience to bring their joint interests into that complete accord which would produce the greatest amount of prosperity and happiness to the island. During the period under review the traffic receipts came to £8,904, the interest received was £2,059, and transfer fees £7, being a total of £10,970, as compared with £14,195 for the half-year ended Dec. 31, 1899. The expenses in the second half of 1900 were £5,502, and in 1899 £6,192, a saving of £690 which reduced the net decline in income to £2,535. Including the balance of £5,204 brought forward, there was £16 175 to be dealt with, from which it was proposed to pay a dividend at the rate of 4 per cent. per annum on the ordinary shares, in addition to the preference dividend at the rate of 10 per cent. By making these payments the carry forward would be reduced by £732. He regretted to announce that they had not yet succeeded in collecting the claim of £8,174 from the Government of the United States in respect of damage done to the Company's cables during the Spanish-American war, nor had the United States Government recognised the Company's concessions, or agreed to the subsidy being paid, the amount overdue now being £4,158. The Board's last communication from the Foreign Office referred to this unfortunate delay, connecting it with the negotiations proceeding between the United States Government and Cuba as to the future government of the island. He moved the adoption of the report and accounts.

Mr. George Keith seconded the motion, which was eventually adopted without opposition, as well as the proposed dividends.

KIDDERMINSTER AND DISTRICT ELECTRIC LIGHTING.

The directros' report for 1900 shows that the total capital expenditure to Dec. 31, on account of buildings and plant for electric lighting, amounted to £14,287. The gross receipts, including the amount receivable from the Kidderminstor and Stourport Electric Tramway Company for dividend on the shares held by this Company, amount to £1 778 which, added to £1,146 brought forward, makes £2,924. After deducting the expenses (including interest on loans), amounting to £767, there remains a net profit of £2,157. The directors propose that this amount should be applied as follows—namely, to dividend on cumulative preference shares for the year 1900, £1,449; to be carried forward, £708. The directors attach to the report a copy of the balance-sheet and profit and loss account of the Kidderminster and Stourport Electric Tramway Company. The net profits in respect of the tramways amounted to £2,108, which added to £92 brought forward, make a total sum available of £2,201. This amount has been applied as follows—namely, to dividend of 5s. 6d. per share on 5,720 shares, £1,573; to depreciation fund, £500; to be carried forward, £128. The public supply of electric energy for lighting and power was begun on Aug. 22, 1900. From the commencement there has been an active demand for light, the actual number of lamps connected to the mains being now equivalent to 5,760 of 8 c.p., and applications have been received for a further 162 8-c.p. lamps. Some of the manufacturers have been induced to try electric motors for driving their machinery, and the installations already made have been attended with most satisfactory results, so much so that the Company has now more applications for power than the present plant can supply. New generating machinery is on order and nearly ready for delivery, which will increase the available power by 600 kw., equal to 800 h.p. The above report will be presented at the meeting to-day.

SOUTH AFRICAN LIGHTING ASSOCIATION.

The report of the directors for 1900 states that the continuance of the war in South Africa has again affected the normal progress of the association at both of its stations, and the bad state of trade, due to the same cause, has prevented any extension of operations. Increased cost of coal has also had to be met to a considerable extent, and as the price of gas was reduced by 10d. in July, 1899, at Port Elizabeth, this factor must be also considered on a comparison of results of the last two years. Notwithstanding these drawbacks, the directors state the results may be regarded as satisfactory, due in a measure to the improved manufacturing results obtained, and a certain increase in consumption at both Port Elizabeth and Grahamstown. Capital expenditure during the year principally arises in connection with the completion of the new coal store.

Digitized by Google

The balance of profit and loss account, including the balance brought forward, and after payment of interest on debentures and income tax. is £11,260. Out of this there has been paid an interim dividend of 4 per cent. (8 per cent. per annum) to June 30, 1900, amounting to £2,400. The directors have placed to reserve £2,000, leaving available a sum of £6,860. The directors recommend a final distribution of 6 per cent.. making 10 per cent. for the year, and the carrying forward of £3,260.

SALISBURY ELECTRIC LIGHT AND SUPPLY.

The directors' report for the year ended Dec. 31 last states that the progress made by the Company during the past year has been satisfactory. The number of consumers has increased from 148 with 6,228 lamps connected, to 210 with 9,795 lamps connected, whilst the sales have increased from £1.165 to £2,320. The profit on the year's working amounts to £1,568. 10s. 4d.. and after writing off the debit balance from last year, £206. 7s. 9d., and payment of £1,230. 19s. 6d. interest on debentures and loans, there remains a balance of £131. 3s. 1d. available for dividend on the ordinary shares. The directors recommend that a dividend be paid at the rate of 3 per cent. per annum on the ordinary shares carrying forward a balance of £21. 10s. 1d. to next account. Of the directors, Mr. Hammick retires by rotation, and being eligible, offers himself for re-election. The auditor, Mr. F. Aston Dawes, also retires, but is eligible, and offers himself for re-election.

APPOINTMENTS VACANT.

Consulting Engineer, Waterford, May 28. Details in our advertisement columns.

Cable Foreman, Keighley, wages 35s., May 29. Details in our advertisement columns.

Resident Electrical Engineer, Maidstone, £250 per annum, May 30. Particulars in our advertisement columns.

Assistant, to take charge of testing continuous-current dynamos and motors. Details in our advertisement columns.

Lecturer in Electro-Technics, University College, Liverpool, £200 per annum, May 31. Details in our advertisement columns.

Engine and Dynamo Attendant, North Wales Counties Lunatic Asylum, 30s. per week. Particulars in our advertisement columns.

Electrical Engineers, South Shields, £350 per annum, May 22. Walthamstow Urban District Council, £300 per annum, May 24. Particulars in our advertisement columns.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Colne.—The Corporation invite tenders for a boiler, mechanical stoker, economiser, overhead crane, transformer, etc. Tenders by May 20.

Glasgow.—The Corporation invite tenders for the supply of electricity meters. Tenders by June 10. Details in our advertisement columns.

Hendon.—The Urban District Council invite tenders for the wiring of the new Council offices. Tenders by June 5. Details in our advertisement columns.

Worksop.—The Urban District Council invite tenders for the supply of 150 electricity meters. Tenders by May 29. Details in our advertisement columns.

Sunderland.—The Corporation invite tenders for the supply of steel plate coal bunkers and overhead gantry. Tenders by May 31. Details in our advertisement columns.

West Stanley (Durham).—Tenders for electric lighting are invited on inspection for new Catholic church, West Stanley. Apply to Rev. J. Thompson. Tenders by June 1

Rochdale.—The Corporation invite tenders for the supply and delivery at Rochdale, Lancs., of copper rail bonds. Tenders by 23rd inst. Details in our advertisement columns.

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection of dry-back marine-type boilers. Tenders by June 8. Details in our advertisement columns.

Motherwell.—The Electric Light Committee invite tenders for cast-iron lamp columns, arc lamps, switches, fittings, etc. Tenders by May 18. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of special (permanent way) track work, cross-over tracks, etc. Tenders by May 25. Details in our advertisement columns.

Dublin.—The Lighting Committee invite tenders for the supply and erection of motors and motor-generators, accumulators, meters, and works wiring. Tenders by June 3. Details in our advertisement columns.

London.—Tenders are invited for a supply of wire copper, lead, zinc, etc. Particulars may be obtained from Mr. Julian Byrne, secretary of the Madras Railway Company 61, New Broad street, E.C. Tenders by May 22.

Hull.—The Electric Lighting Committee invite tenders for 12 direct-current street arc lamps, erected complete with cast-iron posts and spare parts and accessories. Tenders by May 23. Details in our advertisement columns.

Dublin.—The Lighting Committee invite tenders for the supply and erection of main switchboards, sub-station switchboards, transformers, arc lamps, and arc lamp pillars. Tenders by June 3. Details in our advertisement columns.

Exeter.—The Town Council invite tenders for erection of the buildings of their new electricity generating station. Specifications, etc., may be obtained from Mr. Donald Cameron, city engineer and surveyor. Tenders by June 14.

Newcastle-upon-Tyne.—The Corporation invite tenders for supply of 800 tons of tramway rails, fishplates, etc. Particulars may be obtained at the office of the City Engineer, Town Hall, Newcastle-upon-Tyne. Tenders by 18th inst.

Salford.—The Corporation invite tenders for the supply and delivery of additional steel poles, cast-iron bases, etc. (Contract No. 16), in connection with the electric tramways. Tenders by June 3. Details in our advertisement columns.

Long Eaton.—The Urban District Council invite tenders for the manufacture and delivery on seat of two steel Lancashire boilers, engines, dynamos, switchboard, and accessories. Tenders by May 20. Details in our advertisement columns.

Salisbury.—The Urban Sanitary Authority invite tenders for erection of a chimney shaft, 120ft. high and 5ft. internal diameter. Specifications, etc., may be obtained from Mr. Alfred C. Bothams, A.M.I.C.E., Municipal Offices, Salisbury. Tenders by May 25.

Aldershot.—The Urban District Council invite tenders for erection of buildings and shaft in connection with their electric lighting station. Specifications, etc., may be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., surveyor. Tenders by June 4.

Edinburgh.—The Corporation invite tenders for the electric lighting installation, etc., of the first portion of the Colinton Mains Fever Hospital, the number of lighting points being about 1,550. Tenders by June 12. Details in our advertisement columns.

Bermondsey.—The Borough Council invite tenders for the wiring, fittings, and other material required in connection with the installation at the Corporation's electricity supply station and stables, Neckinger, Bermondsey, S.E. Tenders by May 21. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of 5,000 tons of steel girder tramway rails and about 170 tons of steel fishplates, 110 tons of steel tie-bars for tramway rails and 35 tons of bolts and nuts for fishplates, and 5,000 steel tramway poles. Tenders by May 18. Details in our advertisement columns.

Stoke-upon-Trent.—The Guardians invite tenders for electric motors for driving new laundry machinery, also the wiring of laundry buildings, nurses' home, and farm buildings. Specifications, etc., may be obtained from the consulting electrical engineer, Mr. G. R. Peers, A.I.E.E., 96, Deansgate, Manchester. Tenders by 22nd inst.

Digitized by Google

Exeter.—The Council invite tenders for boiler-house equipment, pipes, etc., engine-room equipment, switchboards, connecting cables, coal bunkers and conveyors, and feed and condensing water tanks. Tenders by June 14. Details in our advertisement columns.

Madrid.—Tenders are invited by the Spanish Government for a concession for working a system of electric tramways at Barcelona, the concession already granted having been annulled. Particulars may be examined on personal application at the Commercial Department of the Foreign Office any day between 11 a.m. and 5 p.m. Tenders by June 3.

Bradford.—The Corporation invite tenders for the construction and erection of a five-ton electric travelling crane for their new tram depôt, Leeds-road, Thornbury, to operate on a 500-volt direct-current circuit. Specifications, etc., may be obtained on application to Mr. C. J. Spencer, A.M.I.E.E., tramway manager, 5, Forster-square, Bradford. Tenders by May 18.

Madrid.—Tenders are invited by the Spanish Postal and Telegraph Department for the supply of 30,000 zinc cylinders for the service of the Government telegraph stations. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by June 1.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

London, S.W.—Tenders are invited for the supply of 13,400 tons of steel rails and 958 tons of fishplates for the Queensland Railways. Tenders will be received at the Queensland Government Office, 1, Victoria-street, London, S.W., until 2 p.m. on June 11, endorsed "Tender for Steel Rails and Fishplates," and accompanied by a preliminary deposit of 1 per cent. on the tender. Specifications, drawings, etc., may be obtained at the office of the Agent-General for Queensland.

Kingstown.—The Urban District Council invite tenders for the construction, supply, and erection of boilers, pumps, steam and water pipes, tank, economiser, ironwork, etc., engines, generators, balancer and booster, switchboards and instruments, battery of accumulators and accessories, supply and laying of insulated electric cables, conduits, road frames and covers, street work, drawing-in boxes, feeder switch pillars, etc., fitting of electric light at the electricity supply station, George's-place, Kingstown, supply of electricity meters, demand indicators, and main fuses, supply and erection of arc and incandescent lamps and fittings. Tenders by 30th inst. Details in our advertisement columns.

Ludlow.—The Corporation invite tenders for the supply and erection of one water-tube boiler to be erected and fitted for connection with a refuse destructor, with electric motor, injector, etc.; one ditto, ditto, for a coal-fired boiler, and furnace connected therewith; two quick-revolution compound two-crank self-lubricating engines, coupled direct to compound-wound dynamos, equal to an output of 35 kw. each, with motor-transformers and accessories; steam, exhaust, and feed pipes; overhead travelling crane (six tons); switchboard and instruments; accumulators; electricity supply mains; and public arc lighting and glow lamps, the latter on existing pillars. Tenders by May 20. Details in our advertisement columns.

Tonbridge (Kent).—The Urban District Council invite tenders for the supply and erection of (Section A) boiler-house plant—two Lancashire boilers and accessories, steam pump, injector, and economiser; (B) engine-house plant—two 50-kw. steam dynamos, motor-transformer, and accessories; (C) condensing apparatus and pipework; (D) overhead travelling crane; (E) switchboard and instruments; (F) accumulators; (G) electricity supply mains; (H) public arc lighting; (I) house meters; (K) public incandescent lighting, for the municipal electricity works. The whole bound up in one specification. Specifications, etc., may be obtained by manufacturers at the offices of Mr. Robert Hammond, 64, Victoria-street, Westminster, S.W. Tenders by May 30.

Tedmerden.—The Fielden Joint Hospital Committee invite tenders for the erection and maintenance of telephonic communication between the Fielden joint hospital, the workhouse, and the Urban District Council offices Hebden Bridge, and the Urban District Council offices at Mytholmroyd, and the house of the receiving officer at Hebden Bridge. The line to be a single line 14's copper wire, all Post Office insulators and creosoted poles, and the tender to include the cost of wayleaves, poles, and all necessary apparatus, including switching instruments. Each tender to contain a full specification of work to be done and materials provided, and to be stated in two amounts: (1) the tender for the installation or erection of the communication; (2) the sum for annual maintenance for a term of seven years; (3) also for annual maintenance for the present telephonic communication between the hospital, the workhouse, the gasworks, the market hall and the town hall. Tenders by 21st inst.

RESULTS OF TENDERS.

Watford.—The Electric Lighting Committee have accepted the tenders of Ferranti and Co. for supply of switch gear, at £733, and 12 junction boxes, at £210.

Ashton-under-Lyne.—The Corporation have placed an order for two 250-h.p. direct-current generating units with Siemens Bros. and Co., Limited, at £3,260, with Belliss engines. Fifty offers were received.

Middlesbrough. — The Electric Lighting Committee have accepted the tender of Messrs. Witting Bros., at £3,564, for the engine-house plant required for the extension of the works.

Jarrow.—The Town Council have accepted the tender of the National Telephone Company to put in four new instruments and batteries for £11. 10s., and to maintain the private telephone wire for £7 per annum.

Ayr.—The Lighting Committee have agreed to accept the tender of Messrs. Callender, amounting to £3,625, for the extensions necessary for the introduction of the low-tension continuous-current system into the central area.

Bushey (Herts).—The order for three complete sets of direct-coupled Taunton dynamos and Belliss engines for the Royal Masonic Institution for Boys, Bushey, has been placed with the Newton Electrical Works, Limited, Taunton.

Whitehaven.—The Town Council have accepted the following tenders: Proctor and Cottrill, supply of bitumen, subject to a guarantee of 84 per cent. of best Trinidad bitumen being given; Callender and Co., 200-gallon bitumen boiler, and 1,000 yards 7/18 cable and 1 000 yards 7/20 cable; Electric Construction Company, balancer; Ramsay and Co., two screw jacks; Clarke and Co., disconnecting boxes.

Kingston-on-Thames.—The Corporation have accepted the following tenders: Babcock and Wilcox, construction of underground flues and setting of economisers £1,273, one Wheeler condenser £1 086 one Blake-Knowles cross-compound vertical steam pump £185, one Cochrane oil separator £243, steam, exhaust, feed, blow off, and drain pipes £1,198. 4s.; Carter and Sons, Stalybridge, two Pimbley's economisers, £635. 6s.

Eastbourne.—The Corporation have received the following tenders for building six large and nine small underground transformer chambers, to be constructed of brick or cast iron: Six large (cast iron)—J. Every, Lewes, £519. 6s. 6d., erecting ditto £35 (accepted); Beck and Co., London, £611. 8s. Brick—C. E. Kemp and Sons, Hove, £1,380; Tapner and Co., Hastings, £1,266. Nine small (cast iron)—J. Every, £133. 10s. Brick—Tapner and Co., £121. (Neither tender for nine small accepted.)

Bradford.—The Electricity Committee have recommended the Council to accept the following tenders: British Insulated Wire Company, Limited, at £2,562, for the supply and delivery of lead-covered and armoured cable for lighting main extensions; Phœnix Dynamo Manufacturing Company, Bradford, at £1,403. 18s., to supply and erect at the Bolton-road electricity works a combined motor balancer and boosters, with the requisite switch gear for same; Phœnix Company, at £907. 10s., for the supply, delivery, and erection at the Valley-road electricity works of a 100-kw. motor-generator, with the requisite switch gear for same; Messrs. Lockerbie and Wilkinson, Limited, Birmingham, at £2,163, for the supply and fixing of overhead rails and fittings required at the St. James's Carcase Market.

Newport.—The Corporation have accepted the following tenders in connection with the new power station:

A. S. Morgan and Co., Newport, foundations	£9,349
Hemmingways, Limited, Middlesbrough, structural steelwork	11,955
J. Lysaght and Co., Limited, Bristol, steel flue	712
New Conveyor Company, Limited, Birmingham, coal and ash conveyor	1,987
J. Hitchin and Son, Halifax, overhead traveller	955
Babcock and Wilcox, Limited. London, steam boilers	5,893
Underfeed Stoker Company, London, mechanical stokers	1,198
A. Lowcock, Limited, Shrewsbury, fuel economiser	575
Westwood and Wright, Brierley Hill, water storage tanks	324
Markham and Co., Chesterfield, steam-engines	11,590
Witting Bros., for Kolben and Co., Prague, electric generators	5,170
Worthington Pumping Engine Company, London, condensing plant	5 056
J. P. Hall and Sons, Limited, Peterborough, feed-water pumps	292

The tenders were accepted with the amendment that two instead of three engines for producing 250 kw. be laid down, and the other plant be reduced in proportion. The Walsall Electrical Installation Company's tender for the light at the workhouse, at £1,600, was also accepted.

BUSINESS NOTES.

TRACTION.

Barcelona.—Traffic was resumed on the Barcelona Ensanche y Gracia lines on the 11th inst.

Newport.—The Town Council have decided to erect a power station on Corporation-road for traction purposes only.

Huddersfield.—It has been decided to take a poll of the ratepayers on the question of the running of trams on Sundays.

Wimbledon.—The Urban District Council have resolved to apply in the next session of Parliament for a tramways provisional order.

Steurbridge.—Some enquiry has been made as to the delay in providing the equipment for the electric tramways after setting up the poles.

Walker.—The District Council have decided to further oppose the Tyneside Tramway Company's Bill before the House of Commons.

Digitized by Google

Chatham.—We understand that the British Thomson-Houston Company have now made a start with the work of constructing the electric tramways for the town.

Southend.—It is stated that there is no hope of the tramways being in a sufficiently forward state to enable a service of cars to be put upon the roads before Whitsuntide.

Burton-on-Trent.—The amounts to be borrowed under the Corporation Bill include £52,057 for the construction of the proposed tramways, and £41,900 for tramway purposes.

Cleator Moor.—The Urban District Council have decided that application be made to the Local Government Board for approval of the Council's opposition to the Tramway Bill.

Brierley Hill.—The following gentlemen constitute the new Tramways Committee of the District Council: Messrs. Hancox, Applebey, White, Guest, F. Cartwright, and Morgan.

Heywood.—A sub committee has been appointed to deal with matters relating to the existing tramways, and also to consider and report as to any proposed extensions of the tramways.

Cleethorpes.—In consequence of the tramway operations—the line is being extended to Sea Bank-road in connection with the projected electric service—certain street-widening work has to be done.

Durham.—The Rural District Council have appointed a committee to meet Major Tulloch, chief inspector of the Local Government Board, on the question of the laying down of tramway lines so far as the scheme affects their district.

Parliament.—The West Cumberland Electric Tramways Bill and the London United Tramways Bill have been read a second time in the House of Commons. The Dublin St. James's Gate Brewery Tramway Bill has been read a third time.

Richmond.—The Town Council have sealed a petition to Parliament against the London United Tramways Bill with a view to ensuring the amendment of the Bill in accordance with the agreement between the Corporation and the company.

Spennymoor.—The Urban District Council have decided to support the United Kingdom Tramway Syndicate in the promotion of a provisional order for the construction of tramways on the overhead electric trolley system in the district.

Aberdeen.—The Tramways Committee have decided that the whole of the Great Western-road shall be recausewayed and made ready for electric traction, so that the thoroughfare should be worked electrically from Mannofield to the Holburn junction.

Northfleet.—The District Council have approved the amended plans from the British Electric Traction Company for the proposed Gravesend and Northfleet tramways, subject to certain further amendments. It is intended, we understand, to start work very shortly.

Coseley.—The District Council have received a letter from the British Electric Traction Company, asking for permission to break up the roads under the control of the Council for the purpose of erecting tramway poles. The matter is in the hands of the surveyor.

Newcastle.—The Parliamentary and New Tramways Committee have recommended the Town Council to continue to oppose the Tyneside Tramways Bill before the Committee of the House of Commons, and to see that everything was done to defeat the object of the promoters so far as Walker was concerned.

Wigan.—The Bill promoted by the Corporation for the purpose of conferring on them further powers in regard to the construction of tramways, street improvements, and electric lighting, has passed Lord Morley's committee as an unopposed measure. The town clerk proved the preamble, and the Bill was ordered for third reading.

Jarrow.—The Light Railway Commissioners, in a recent communication to the Jarrow Town Council, intimated that they had recommended to the Board of Trade the Durham Electric Supply Company's proposed route for light railways so far as it applies to the borough, in preference to the alternative route suggested by the Corporation.

Ayr.—The Corporation have fixed upon the scale of wages to be paid their tramway employés. So far the weekly wages bill will amount to £42. The Town Council have decided that the trolley poles shall be placed between the tramway lines through the town. When the electric tramway is opened there will be a full service of cars on Sundays.

Leith.—The Corporation have received a letter from the secretary to the Edinburgh Street Tramways Company, asking if it be the desire of the Corporation to enter into negotiations with the company with the view of introducing electric haulage on the Leith tramways. The General Committee have resolved to take no action in the meantime at least.

Aston Manor.—Mr. Councillor Gittings has been appointed chairman of the Tramways and Electric Light Committee of the Urban District Council for the ensuing year. Steps are being taken to obtain the approval of the Board of Trade to the purchase by the Council of that part of the undertaking of the Birmingham and Aston tramway as authorised by the order of 1880.

St. Helens.—It was stated at the Town Council meeting on Wednesday that on the tramway account last year's estimate of £3,894 was overspent by about £1,700, including £800 for interest and sinking fund and £100 for ground rent. The estimate for next year was £6,937. The total expenditure on this account was charged against the rent and interest payable by the tramways company.

Ashton-under-Lyne.—A sub-committee appointed for the purpose has visited a great number of towns in kingdom, and it was stated at the monthly meeting of the Town Council had been much impressed by the general system in vogue at Southport. The Ashton scheme would be practically like the Southport one in regard to overhead trolleys, and both single Californian cars and double-deckers would be used.

Stockport.—The Market-place tradesmen are agitating for better tramway facilities. At a largely attended meeting recently it was resolved: "That the Tramway Committee of the Stockport Corporation be asked to adhere to their original pledge, that the trams from Bredbury should go by Newbridge-lane and Millgate to the Market-place; also that the Hall street trams should go down Churchgate to the Market-place."

Darwen.—At the quarterly meeting of the Town Council the Chairman of the Electricity and Tramways Committee stated that there was a loss in the electricity department during the past year of £886, and on the tramways of £604. The capital in the electricity department amounted to £38,000, and the receipts only totalled £3,000. He thought they ought to have a moderate profit at the end of the next financial year.

London County Council Tramways.—The Select Committee of the House of Commons presided over by Mr. Seale-Hayne continued this week the consideration of the Bill of the London County Council providing for numerous tramway extensions and junction lines, principally on the south side of the Thames, the whole to be worked, together with the existing lines, by electricity on the conduit system, under the powers of the Act obtained last year.

New York Tramway Strike.—Advices from New York state that serious rioting has broken out in Albany, New York, where the employés of the city tramway companies are on strike for higher wages. The rioters got beyond control of the local authorities, and the military had to be called out. In Troy, New York, the tramcar strikers are also spreading terror. It is said they have torn up the tracks and demoralised business. A large number of troops are on the spot.

Leigh.—The South Lancashire Tramways Company have notified the Town Council that they are prepared to enter into arrangements to provide a supply of electricity in bulk to the Corporation, and that the company's generating station would be at Atherton instead of at Leigh, and that they would lay the cables from Atherton to the borough of Leigh free of charge. The Town Council have decided to reply that they expect the company to fulfil their promise to erect their generating station at Leigh.

Dundee.—At this week's meeting of the Tramways Committee Mr. Wm. Mackison, the burgh engineer, reported satisfactory progress in connection with the tramways works. A recommendation that block signals should be placed at South Tay-street and West Port, at a cost of about £85, was approved. A suggestion by the manager to the effect that shelters should be placed at Ninewells of the same kind provided at Polepark also received the approval of the committee, and instructions were given accordingly.

Waterloo-with-Seaforth.—At the last meeting of the Urban District Council it was stated, in connection with the tramways, that the surveyor, having obtained the consent of the frontagers concerned to the construction of a new loop south of Cambridge-road, the Board of Trade had also given their consent. It was further stated that the Liverpool Overhead Railway Company had given instruction for overhead guard wires to be fixed in addition to the guard strips, in accordance with the latest ideas of the Board of Trade.

Liverpool.—An inquest arising out of the running over of a young child in Liverpool who strayed on the electric tramlines, resulted in a verdict of "accidental death." The tramway manager stated that the Corporation had carried one hundred million passengers since electric power was used, and, compared with horse cars, the percentage of fatalities were fewer by electric than by horse cars. As to the best kind of front guard to tramcars, the manager favoured a guard which pushed the object clear off the track instead of picking it up.

Scarborough.—At the monthly meeting of the Town Council attention was drawn to a letter from the British Electric Traction Company, Limited, making proposals for the introduction by the company of a system of electric tramways for Scarborough and district. The matter had been referred to the Tramways Sub-Committee, who were considering it. It must be remembered, however, that the Corporation had pledged its word to Parliament to introduce a Tramways Bill next session, and this meant that they must commence the work of preparation at once.

New General Traction Co.—The report of this Company for the year ended March 23 states that the gross profits were £41,087, and £37,031 was brought forward. The directors propose to transfer £7,000 to reserve against goodwill and £10,000 to the general reserve. A distribution is proposed of 4 per cent. for the year on the ordinary shares, leaving £41,136 to be carried forward. To meet the cost of the competition of the Philadelphian system, and to cover the amount of the outstanding loans, the directors propose to issue £200,000 of 5 per cent. redeemable debentures.

Darlington.—On the completion of the agreement between the Corporation and the Imperial Tramways Company for the purchase of the company's undertaking for £7,500, the Council will have to submit a scheme for electric tramways. It has been intimated by the Light Railway Commissioners to include Houghton-le-Skerne and Cockerton outside villages. An adverse

Digitized by Google

movement is being promoted by opponents of municipalisation, and a requisition for a public meeting has been sent to the Mayor. A preliminary meeting of the ratepayers' association has been held to consider the matter.

Returns.—The Board of Trade's customary sessional returns shows the total number of Bills deposited for the present term of Parliament relating to railways, canals, and tramways, and electricity, gas, and water undertakings to be 190, representing £88,738,900, as compared with 213, representing £94,534,200 last year. The number of measures concerning electricity is 11, and the proposed capital amounts to £12,549 300. Tramway Bills number 36, and stand for £4,433,500. In addition to these measures there are 166 applications, requiring £4,101,500, for provisional orders, of which 108, taking £1,994,600, are for electric lighting.

Swindon.—The Corporation were engaged on Tuesday in considering the report of Colonel Yorke, Board of Trade inspector, with regard to his inspection of the routes selected for the proposed electric trams, and it was decided, subject to the arrangement of details, to accept the recommendations of Colonel Yorke. The chairman of the Tramways Committee, with the engineer (Mr. Lacey) and the solicitor, were directed to interview the Board of Trade on the subject. The plans of the building for the electric generating station have been approved by the Works and Plans Committee, and tenders for the erection of these buildings will be at once advertised for.

Paisley.—The enquiry under the Private Legislation Procedure (Scotland) Act into the rival Corporation and private tramway schemes for Paisley came to a conclusion before the Parliamentary Commission presided over by the Earl of Camperdown last week. The Chairman said the Commissioners had decided to recommend that the Corporation tramways order be refused and that Mr. Murphy's Bill might for the present proceed. At some time or another the Commissioners intended to require that in some form or another a guarantee be given for the completion of these tramways. Mr. Murphy announced, through his counsel, that he was prepared to give his guarantee.

Preston.—The Town Council have approved the report of the General Committee in regard to the proposed tramways recommending the adoption of the low-tension current system with overhead trolley wires, and suggesting as a convenient site for the generating station land near the Corporation destructor in St. Paul's-road. They further recommended that instead of taking advantage of powers for a 4ft. gauge already obtained, a gauge of 4ft. 8½in., as employed in most towns, should be adopted, and that the Corporation should construct and work the tramways themselves, "believing, although no trustworthy forecast could be made, that the service might be made to pay."

South Lancashire Tramways Bill.—This Bill came before the committee of the House of Lords last week, when the chief opposition raised was on behalf of the Corporation of Salford, who sought special clauses for the protection of their gas and water mains from the possible danger of electrolysis. For the promoters it was contended that the Board of Trade clause already inserted in the Bill gave the Salford Corporation every reasonable protection. In the end, Lord Ducie (the chairman) announced that the committee had determined not to insert the clauses asked by Salford, and passed the Bill in its original form, including the right to supply electrical power to local authorities within the area served by the company.

Speed of Motorcars.—At the annual general meeting of the County Councils' Association, held on Wednesday at the Westminster Guildhall, under the presidency of Sir J. T. Hibbert, the question of the relation of roads to motorcars was raised. It was stated that 12 county councils were in favour of the reduction of the pace of motors from 12 to 10 miles, and 13 were against any reduction. A letter from the secretary of the Automobile Club expressed the view that there should be no alteration in the regulation as to speed, but that vehicles should not be driven to the common danger, and that the proposed numbering would seriously injure the motor industry of the country. No resolution was put to the meeting.

Limerick.—The Town Council, having sanctioned the scheme of the Limerick Tramways Committee, have resolved that it may be modified as follows: "That instead of a period of 21 years for which the use of the streets is to be given, the streets are to be given in perpetuity, with the option of the Council to purchase at the expiration of 50 years or at any time thereafter, any difference in price to be settled by arbitration, and that instead of a revision as to wayleave every seven years the tramway company are to pay £50 per mile per annum wayleave, and in any event until they paid 6 per cent. dividend, and after that to pay to the Council £50 per annum for every 1 per cent. dividend paid by said company in addition to the above wayleave."

Blackpool.—The Corporation Bill came before a Select Committee of the House of Commons this week. The measure includes a proposal for the extension of the tramway from Waterloo-drive along Middle-lane to the borough boundary at Squires Gate-lane, and this was opposed by the Blackpool, St. Annes, and Lytham Tramways Company, on the ground that this tramway, running parallel to Lytham-road, was intended to compete with the line leased by the Corporation to the company, and would intercept and divert traffic from the company's line. Certain owners and occupiers of properties also petitioned against the Bill. Evidence testifying to the advantage attending the development of the tramways in the town was given, and the committee adjourned.

Bicycle-Carrying on Light Railways.—The question of bicycle-carrying on light railways was raised before Sir Courtenay Boyle on Tuesday in connection with the South Yorkshire light railway. On behalf of the Cyclists' Touring Club it was proposed that a bicyclist should be able to have his bicycle carried the whole distance—six miles—or any part thereof, for 3d. On behalf of the promoters it was urged that no great railway company or light railway company had been compelled to carry bicycles by passenger trains, and if they were carried as luggage, then the railway company would be liable if they were damaged. Sir C. Boyle said that he was favourably disposed to the bicyclist, but it would require careful consideration before deciding that a bicycle should be taken as passenger's luggage, and he should reserve the point.

Newcastle's New Trams.—At a meeting of the Tramways Committee last week, Mr. Hopkinson, the electrical engineer, reported upon the general progress of the work of the new tramways. He stated that the two boilers at the power station were already set, and that two more were ready for completion. The progress of the work was satisfactory all round. Twenty cars were completed and would be delivered within a week or two. It was thought they would be able to run cars in certain sections by the end of October. A proposal to introduce steam trams into districts where lines are now completed has been rejected, the strong feeling being expressed that whilst it might be necessary to make some arrangements to run cars on the completed lines, steam power was not considered suitable.

Leicester.—Mr. E. Manville, the expert called in to report on the question of electric traction for the Corporation tramways, has submitted his report, in which he recommends the adoption of the overhead trolley system and the erection of a separate power station for the purposes of the tramways on the Lero site. He estimates the cost of constructing the system on the overhead trolley system at £299,306, as against £644,925 on the conduit system. The difference in cost between the two systems is therefore £345 619, exclusive of feeders. Mr. Manville's estimate of the cost of the separate power station on the Lere site is £75,854. The Tramways Committee, we understand, after consideration of this report, have unanimously agreed to recommend the sub-committee's scheme to the Council for adoption, and also that Mr. Manville be appointed consulting electrical engineer.

Plymouth.—At the meeting of the Borough Council on Monday it was stated that the deficit on last year's working of the tramways, although reported to be £61, had been brought down to £7 by the payment of £54 regarded as doubtful. Practically, therefore, there was no deficit on the year's working, and that in spite of the fact that they were paying £600 a year more for the electric current than they ought to pay, the average price in other parts of the country being 2d. per unit, while they were paying 3½d. This year it was estimated the receipts from the tramways would amount to £25,000 and the expenditure £19,000, leaving a profit of £6 000, so that in 1903 they would be able not only to wipe off the deficit, but contribute a very substantial sum in relief of the rates. It was expected to get £2,000 extra from the Prince Rock section, £2,000 from the Sunday trams, and £2 000 from the ½d. and 1½d. fares, so that a great deal of the profit was due to new management and not to working on old lines.

Bolton.—The accounts of the tramways department of the Corporation have just been issued for the past year. The total income for the year ended March 31 in traffic receipts is £69,147, and the following are the items of expenditure: maintenance of line, etc., £3,094; rents, rates, etc., £2 143; interest account, £6,623; traffic expenses account, £735; management account, £1,616; maintenance of equipment, £680; and of cars, £3,011; miscellaneous expenses account, £634; charge for electric power, £10,107; compensation, etc., account, £508; wages of drivers, conductors, etc., £13.412; wages of car cleaners, labourers, etc., £4.405; track (construction), £8 227; land, buildings, etc., £2,684; electrical equipment, £2 454; cars, etc., £2,763. The total liabilities are stated at £281,353, against which the tramlines are estimated to be worth £94,621; land, buildings, and goodwill, £86,786; overhead equipment, £46,644; cars, £24,873. There is a cash balance of £25 798. The committee have decided to devote £5,742 to the relief of rates.

Carlisle.—Colonel Yorke, of the Board of Trade, has made an inspection of the tramway lines on Eden Bridge with reference to the question which has been raised as to the restriction at present in force preventing tramcars from passing each other or stopping to pick up passengers on Eden Bridge. Colonel Yorke indicated that the question of the regulation of the traffic on Eden Bridge was one rather for a by-law of the County Council than for an absolute regulation by the Board of Trade; and it was, therefore, taken for granted that if the County Council, with the concurrence of the tramways company and the parties concerned, framed a by-law which would so regulate the traffic of the bridge as would suit the convenience of the majority of the travelling public, it would be approved by the Board of Trade. It would be an improvement if the tramlines were made double from the bridge to the top of Stanwix Bank, or, at all events, some distance up the bank, and the cars could have waited there to pass each other instead of, as at present, at the cattle market or at Eden Mount. The inspector, speaking of the headlights carried by cars, said they ought all to be white.

Wolverhampton.—The Town Council have confirmed their resolution in committee to the effect that the proposed Corporation tramways be equipped with the Lorain underground system of electric traction, details of which were given in our last issue. On Tuesday afternoon a deputation of manufacturers, tradesmen, and others waited upon the Tramways Committee for the purpose of laying before them their views with respect to the break in the tramway communications between Wolverhampton

Digitized by Google

and Bilston, Willenhall, Sedgley, and other adjoining neighbourhoods. The Chairman, in reply, said the points put forward would receive the very serious consideration of his committee. As to the suggestion with regard to making a temporary vehicular service between Wolverhampton and the outlying districts by means of 'buses, brakes, and so on, corporations had no power to subsidise any system of that kind. He feared also that it would be some time before the British Electric Traction Company would be of much use in regard to the conveyance of passengers between the boundaries of Wolverhampton and the adjoining townships of Bilston and Willenhall.

West London Tramways.—The 2d. fare charged by the London United Tramways Company for the journey from Shepherd's Bush to Kew has given rise to considerable local discussion. At a meeting of the Works Committee of the Chiswick District Council the opinion was reported that whatever the legal view of the case might be, there was no doubt that Mr. Clifton Robinson had a moral obligation to reduce the fares. It was decided that a full statement of the case be sent to the Kingston Corporation and the District Councils of Ealing and Isleworth, or any other local body which was included in the tramway company's Bill before Parliament at the present moment, with an intimation that, if desired, the clerk would attend and give evidence before the committee "as to the way the tramway company kept faith." In consequence of the annoyance caused to the inhabitants of the main roads through which the new lines run by the continual ringing of bells, and on account of the accidents which have recently occurred, the Hammersmith Borough Council have made representations to the company with reference to the speed at which the trams travel, and also as to the unnecessary ringing of the bells.

Cardiff.—At the Tramways Committee meeting the Town Clerk explained that the negotiations with the tramways company as to the terms of relaying the lines, which would affect the final purchase, had been delayed. Under Section 48 of the Local Government Act, the Corporation had power to refer to arbitration for settlement, and in case of difficulty it would be policy to refer. It was decided, however, to again communicate with the company and reopen negotiations, mentioning prices. At the Town Council meeting on Monday, on the motion that the town clerk be instructed to apply for the necessary provisional order authorising the extension of the tramlines on Cathedral-road northwards to a point on that road representing the junction (at the northern end) of Mortimer-road with Cathedral-road, an amendment was proposed, and ultimately adopted, that the committee be instructed to take into consideration the extension of the system in the whole district, and report thereon, with a view of obtaining a provisional order to include the whole. With reference to the reconstructing of a section of the Cathays tramline the company have agreed that the work shall be carried out in accordance with the Corporation's specification. It is hoped that a portion of the electric system—that to the docks—will be in vogue on Jan. 1 next year.

London Underground Railways.—On Tuesday Lord Robert Cecil, K.C., laid before the Joint Parliamentary Committee on Underground Railway Communication in London the proposals of the Central London Railway for making a single-line loop at each end to afford a more frequent train service. Sir Henry Oakley, chairman of the line, explained that the Central London Railway Bill of 1892 gave powers for the extension of the line to Liverpool-street, which had not been carried out. The Central London was now in the position of having its trains, morning and evening, greatly overcrowded. They had, therefore, come to the conclusion that it would be wiser, in the general interest, to have a loop, and so secure connection with Liverpool-street by a circle, and enable the trains to run continuously and the present delay be obviated. The manager believed that by the proposed improvement they would be able to work a service every two minutes in the busy times of the day, thereby adding some 60 or 70 trains a day. At present about 700 trains a day were run. The closest approach to any other service by the extension would be near by Liverpool street, where it would be 45ft. to 46ft. below the Metropolitan. It was proposed to make a subway to Broad-street and the Great Eastern Stations, and also give access to the street. Mr. Littler, K.C., then explained the scheme of the Charing Cross, Euston, and Hampstead Railway. The new proposal was to extend the line from Kentish Town, by an interchange station, to Highgate, and to continue the Hampstead branch to Golder's Hill. It was proposed to have 13ft. tubes to prevent vibration. Sir Douglas Fox, C.E., explained that with a 13ft. tube ordinary locomotives would be replaced by motors attached to the axles of the cars, but not necessarily to every car. Unless parliamentary sanction was given for the change from the 11ft. 6in. tube to the 13ft. tube, the promoters would be at a loss of £50,000 to £60,000, the orders having been given for the machinery for the larger tube. The case of the City and North-Eastern Suburban Railway was next considered, and the committee adjourned.

Sheffield.—With reference to the threatened strike of the Corporation tramways employés in consequence of the summary dismissal of Mr. G. E. Francis, the depôt foreman at the Tinsley and Queen's-road car-sheds, on the ground of discourtesy, the following is the statement of Alderman Clegg, the chairman of the Tramways Committee, to the Town Council on the subject: "For some considerable time past Mr. Fell (the tramways manager) has complained to me about the conduct of Francis towards himself, and also as to his dissatisfaction at the way Francis's department at the Tinsley car-shed had been managed. Certain orders were given to endeavour to remedy this state of affairs. As, however, matters did not improve he again spoke to me, and as I saw it was necessary to take some decisive step to enforce discipline, it was with my entire sanction and approval that a month's wages in lieu of notice should be paid to Francis and his services dispensed with. The grounds for this action were as follows: (1) insubordination; (2) inciting the men to needless agitation; (3) undermining the authority of the manager; (4) personal discourtesy; (5) untruthfulness; and (6) mismanagement. It is well known to the Council that I have always been most favourably disposed towards the employés, always giving a sympathetic hearing to any of the supposed grievances and complaints, and have at all times done whatever I could to promote their advancement and welfare. I am greatly disappointed at the attitude which the employés have taken up in interfering with a question which did not affect themselves in any way whatever, and can only conclude that similar influences were brought to bear on them as on a former occasion when they indulged in a similar threat. I desire, however, that it should be distinctly understood, so long as I am chairman of the Tramways Committee, that we shall be masters, and we shall allow of no interference or dictation with the working and regulating of the undertaking, or as to our dealing with any of the officials or men, and that I shall advise the committee to act on the following lines: (1) that the committee or manager have the right to terminate the services of any official or employé without giving their reasons therefor if they think it is to the interest of the undertaking to do so; (2) that any interference with the exercise of this right by the employés will be looked upon as unjustifiable and subversive of discipline; (3) that the doctrine that employés are entitled to know the reasons of the termination of a man's service or dismissal either by the committee or manager is untenable, and cannot and will not be recognised or tolerated; (4) that so long as the committee have confidence in their manager they will support him in his actions and his management. At the same time I can say, speaking not only for myself, but, I believe, for every member of the committee, that I am prepared to receive and consider impartially any complaints or grievances the men may think they are suffering under if they are brought forward in a legitimate and proper manner. I desire to express my warm thanks to Mr. Councillor Copley (secretary of the Enginemen and Cranemen's Society), and Mr. Temperton (secretary of the Hackney Carriage Association), and also to Messrs. Councillors Hobson and Shaw, for the efforts they put forth, and for the sound and sensible advice they gave to the men." The expressions of opinion embodied in this statement, with which we entirely agree, were unanimously adopted.

Warrington.—In the report submitted by Messrs. Preece and Cardew at last week's meeting of the Town Council, they gave their reasons for selecting the overhead trolley system as that most suitable for the proposed tramways in the borough. They first pointed out that the available systems of electrical working of tramcars are: (1) the overhead trolley system, (2) the conduit system, (3) the surface-contact system, (4) the accumulator system. The first system had incontestably the following advantages over systems 2 and 3—viz., much lower first cost, greater simplicity, less liability to derangement, greater facility for repair, far less disturbance of streets during construction. The only objections that could be lodged against it in comparison with the competing systems were the æsthetic objection that the overhead wires were a disfigurement to the town, and the possibility of danger. The first objection was not a serious one, except in the case of fashionable resorts, where the attractions and amenities of the place were the first consideration. The overhead construction, if properly erected and maintained, was not offensive, and was certainly less open to objection than the overhead wires of the Telephone Company, which cross at all angles, and with no order or regularity. The second objection was far more reasonable, and had been lately emphasised by the unfortunate accident at Liverpool. The prevention of all risk of accident to the public using the streets had engaged their serious attention. This subject, moreover, was one which Major Cardew, as electrical adviser to the Board of Trade, had especially to study. The only accidents that had occurred had been due to the use of imperfect guarding arrangements against the fall of crossing wires, either with or without such a fall occurring. In the case of Warrington, no such heavy spans of crossing wires as in the case of Liverpool existed, and the guard wire which had been specified were amply strong and thoroughly earthed. They suggested that these crossing wires should be carefully watched. If possible, they should be put underground by arrangement between the Corporation and the Telephone Company, as had been already provided for in the centre of the town, or should this not be practicable, the Telephone Company should be requested to cable their wires in all cases where more than a few wires cross at one spot. In referring to the other available systems, the engineers pointed out that with regard to the accumulator system, wherever it has been tried it has been found to be excessively costly in working and maintenance, and to have many other objections, such as the discharge of disagreeable acid fumes in the cars, the rapid corrosion of all ironwork, the great increase of dead-weight to be carried, loss of time in changing, etc. Proceeding to refer to the conduit system, it is pointed out that the advocates of the open-conduit system themselves state that where a single-track line cost £5,300 per mile for an overhead trolley road, the conduit construction would cost £11,000. In the above price no allowance was made for obstructions, such as sewers, gas and water pipes, which had to be diverted, and this might vary from several hundreds to several thousands per mile. During construction the road in question had to be entirely blocked for several weeks, an inconvenience to trade which nothing but the greatest after advantages could warrant. It was further pointed out that the

Digitized by Google

rails forming the side of the slot usually exposed a width of 6in. of iron, and was objectionable to horses and ponies, whose shoes varied from 3¼in. to 6in. in width. From the engineers' point of view the open conduit was more difficult to work satisfactorily than the trolley wire, because the mains, being hidden, were so difficult to inspect. The draining of the conduit was a very important matter, and even in the most carefully designed conduits cleaning at prescribed intervals was necessary. The cost of this cleaning varied a good deal in different localities, but it was between £50 and £100 per mile of track. In conclusion, Messrs. Preece and Cardew referred to the surface-contact system stating that the greatest defect of surface-contact systems hitherto has been the risk of one of the studs remaining charged after the car has passed over it, involving great danger of a serious accident from a horse stepping on it.

The Manchester-Liverpool Monorail.—The enquiry into Mr. Behr's scheme for the construction of an electric express railway between Manchester and Liverpool was again before the House of Lords Committee presided over by Viscount Falkland this week. On behalf of the promoters, Mr. Balfour Browne made a statement in regard to the possibility of the proposed monorail line being turned into an ordinary railway. On that point he was authorised to say absolutely that the promoters did not intend to use their powers for any purpose but the monorail, and that the word "may" in the Bill should with that view be turned into "shall." It had further been suggested that if they constructed the carriages in the way proposed, the centre of gravity would, contrary to what their witnesses said, be above the monorail, and that in that way there would be danger. As to that he was perfectly willing to agree that no carriage should be run upon the railway unless the centre of gravity was below the monorail, and this should be proved to the satisfaction of the Board of Trade before any carriage was run on the railway. Among the witnesses called in support of the opposition of the Salford Corporation were Mr. Joseph Corbett, borough engineer; Mr. W. Melville, engineer-in-chief to the Glasgow and South-Western Railway Company; and Sir Douglas Fox. The last-named gentlemen stated that the number of persons displaced and the interference with property were just as great under the present scheme of cut-and-cover as was the case last year with the viaduct proposal. Replying to questions as to the mechanical details and arrangements of the scheme, Sir Douglas said he did not think it would be safe to run round curves of 30 or 37 chains radius at the high speed suggested unless the structure were tilted. Where they had, as there was here, a car with a great number of wheels of varying diameters, and running, therefore at very different speeds, the effect would be to produce great vibration both on the passengers and on the permanent way. It was a misnomer to call Mr. Behr's proposal a monorail, for there were really five rails. The monorail system, so far as it had been applied, was mechanically complicated, involving a large number of wheels of different diameters, and he could not see where the advantage came in. He believed that electrical traction, when properly applied, had a great future, but he did not consider that Mr. Behr's was a practical method of applying such traction at high speeds. The proposed method of transmitting the power by chains was not, in his opinion, practical. If high speeds were to be obtained by means of electricity, it must be by taking advantage of rotary motion as against reciprocating action. The permanent way, he believed, would be extremely difficult to maintain in proper working order. The car was the weakest in design he had ever seen. It was cut in two by the running wheel and rail, and it was caught only at the top. It was easy to conceive that with a severe or sudden pressure it might come in halves. Taking all the circumstances into consideration, he was of opinion that a speed of at least 120 miles an hour would have to be attained in order to cover the distance between Liverpool and Manchester in 20 minutes. With regard to brake power, they knew what was possible at speeds up to and between 60 and 80 miles an hour, but he believed there was nothing known with certainty as to the action of brake power at higher speeds than those. As far as he knew, everything was experimental. Speaking with an experience of 40 years of railway matters, he was of opinion that the proposed line could not be constructed for the estimate of £50,000 a mile. He did not say that Mr. Behr's system might not work very well at slow speeds for certain purposes, such as running up a mountain side, but he looked upon it as purely experimental as applied to traffic of this kind, and he could not see how it could possibly be made to succeed. He was afraid that if this Bill were sanctioned, the proposed railway would be a failure, and it would set back what they all so much desired to see—the introduction of electrical traction at high speed. Mr. Francis Fox, C.E., Mr. C. A. Rowlandson (chief engineer of the Great Central Railway), Mr. A. Ross (chief engineer of the Great Northern Railway), and Mr. S. H. Short (technical director of the English Electric Manufacturing Company, Preston, and formerly professor of electrical engineering at the University of Denver, Colorado) gave corroborative evidence. Mr. Stephen Sellon, chief engineer of the British Electric Traction Company, Preston, gave it as his opinion that if the Bill were sanctioned it would be detrimental to the best interests of electric traction. The scheme now before the committee he considered both crude and impracticable, fanciful and doubtful, and as absolutely valueless for the purpose for which it was intended. With the high speed of 120 miles suggested and the small curves proposed, the action due to centrifugal force would be sufficient, he said, to turn over the whole structure on which the running rail was held. Prof. C. A. Carus-Wilson also gave evidence against the scheme. He did not see how the car could fail to come off the rail if it ran at a speed of 110 miles an hour round curves of from 30 to 47 chains radius, as proposed in the Bill. Sir W. Pollitt, general manager of the Great Central Railway Company, saw no justification on any ground of public convenience for the proposed line, and, in view of the efforts which the existing companies had successfully made to give a good service, he thought it would be a great hardship if they were to be deprived of the very moderate return they now received by the possible success of this experiment. He also believed the line would be a huge financial failure; but, nevertheless, it would do a great injury to the Cheshire Lines. The committee adjourned.

LIGHTING AND GENERAL.

Leyton.—Sanction has been obtained to the borrowing of £5,000 for electric lighting.

Wheatley.—The Urban District Council intend to support the Yorkshire Electric Power Bill.

Darwen.—The Corporation are to spend £15,000 in additional works and mains for electric lighting.

Manchester.—Mr. W. E. Warrilow has been appointed as junior mains assistant to the Corporation.

Bristol.—The Electrical Committee have found it desirable to spend £850 on an addition to the site of the Avonbank estate.

Ashford.—The Council are consulting Mr. Thos. Hesketh in connection with the carrying out of their electric lighting provisional order.

Cable Rates.—The rate for telegrams to Madeira and St. Vincent (Cape Verd Islands) has been reduced respectively to 1s. and 2s. 2d. per word.

Bath.—The surveyor has been instructed to report upon the question of replacing at a certain hour the large arc lights by two incandescent lamps.

Doncaster.—The Corporation have withdrawn their opposition to the South Yorkshire Electric Power Bill and the Yorkshire Electric Power Bill.

Thornhill.—Mr. Brown has been empowered to give evidence in support of the Yorkshire Electric Power Bill without prejudice to the opposing measure.

Heywood.—We understand that the erection of machinery at the generating station will be commenced almost immediately. The crane has already been fixed.

Kinver.—The British Electric Traction Company have been asked if they intend to light up their terminus, and also on what terms they would supply the current to Kinver.

Willesden.—At the last meeting of the Willesden Guardians Mr. Morgan Williams, M.I.C.E., was appointed to the post of consulting engineer to the new Willesden Infirmary.

Middlesbrough.—The Electric Lighting Committee have decided to borrow £34,100 for electrical work, and to accept a number of tenders, details of which appear in another column.

Eastbourne.—Combined arc and ventilating columns of an ornamental pattern like that adopted by the Brighton Corporation are to be purchased for the front, at a cost of £28. 10s. each.

Pemberton.—Mr. Moorfield has been appointed chairman of the Electric Lighting Committee, who have just completed a loan of £10 000 at 3§ per cent. Steps are being taken to obtain another £10 000.

Ealing.—An extension of mains is to be made to Stephen's-road at a cost of £262. 10s., the owner of the houses there having expressed his willingness not to fit them for gas except for heating purposes.

Farnham.—The Urban District Council have decided to consult Sir William Preece with regard to the offer received by them from Edmundsons' Electricity Corporation to carry out the electric lighting of the town.

Commercial Telegraph Construction Syndicate, Limited.—At an extraordinary general meeting of the above syndicate Mr. Cecil Quennell, 77, Angel-court, Throgmorton-street, E.C., was appointed liquidator.

Brandon.—The special committee of the Urban District Council appointed to consider the electric lighting question so far as it concerned Esh and Waterhouses have recommended 55 lamps of 32 c.p. each at a cost of £2. 5s. each.

Dublin.—A further expense of £333 on extensions in connection with the added lighting area, which was finally agreed to, caused as much or more debate at the City Council on Monday as the previous resolution affecting £234,500.

Keswick.—It appears that the electric light company are stopped in their work of placing arc lights in the town owing to the lamps not having been delivered. The company are ready to place them as soon as they are received.

Chefoo-Taku Cable.—The Eastern Extension and Great Northern Telegraph Companies' repairing steamer left Woosung a few days ago for Chefoo to lay the first portion of the proposed duplicate cable between Chefoo and Taku.

Trowbridge.—At the last meeting of the Urban District Council the Clerk reported the receipt of a letter from the parliamentary agents, Messrs. Baker, Lees, and Co., enclosing a print of the Bills confirming the provisional order.

Malling.—The National Telephone Company are quoting £105 for connecting the hospital to the clerk's office, also to the doctor's house, and on to the workhouse, with free maintenance for the first six months and an annual charge of £4 afterwards.

Barnet.—The Urban District Council have asked the electrical company to light the new area (as at present lighted by gas

Digitized by Google

lamps), including May's-lane-road, up to and including Duck's Island, and also to state terms for further extensions.

Christ Church, Oxford.—The governing body of Christ Church have decided to carry out the electric lighting scheme of their consulting engineer, Mr. Morgan Williams. The contract has been placed with Messrs. Hill, Upton, and Co., of Oxford.

Dundee.—A sub committee has been instructed to make enquiries with regard to the proposed municipal telephone system. If necessary, the Glasgow engineers will be invited to Dundee to inspect and give estimates of the cost of municipalisation.

Fulham.—The Council propose to enter into an agreement with the Postmaster General, in respect of the laying of telephone mains and distributing pipes in future, providing for a deposit of complete plans with the Council before any works are carried out.

Engineers' Wages.—The Amalgamated Society of Engineers recently approached the employers in the East London district with a request for 2s a week increase in wages, and obtained an immediate advance of 1s. a week, the other 1s. to be discussed six months hence.

Hove.—A motion in regard to revision of charges for current which was on the agenda for last week's meeting of the Town Council was withdrawn, as negotiations are on foot with regard to the electric light company, and the Council will deal with the whole question.

Burton-on-Trent.—The Gas and Electric Light Committee reported at the last meeting of the Town Council that an extension of the electric mains along Horninglow-street had been decided upon, to supply seven houses and a motor, a return of 20 per cent. on the outlay being guaranteed.

Horsham.—The Local Government Board have informed the Urban District Council with regard to the proposed exchange of sites for the electric lighting station that they will issue fresh sanction to the borrowing of £13 706 for the purposes of electric lighting, and £300 for the purchase of land for depôt purposes.

London Gazette.—The first meeting in the estate of G. F. Cook (trading as G. F. Cook and Co.), lately residing at Lightcliffe, Yorkshire, will be held on May 21, at 11 a.m., at the official receiver's chambers, 31, Manor-row, Bradford, and the public examination on May 22, at 10 a.m., at County Court Manor row, Bradford.

Metropolitan Electric Supply Co.—When the Bill "to confer further powers on the Metropolitan Electric Supply Company, Limited, with respect to the supply of electrical energy and for other purposes," came before a Select Committee of the House of Commons this week, Mr. John Conacher, general manager of the promoting company, said that they were now increasing the capacity of that station at a cost of £85,000. The preamble was proved on Wednesday.

St. Pancras.—The accounts of the Electricity Committee of the Borough Council for the past year show a gross revenue of £49,329, making an increase of £4,449 compared with 1899. £3 207 of which is due to public lighting and £1,242 to private lighting. The total units sold during the first half of the year were 1,056,613, at an average price of 4·48d. per unit; and in the second half, 1,239,773 units, at 3·63d. The net profits amounted to £2,921, increased to £4,056 by the balance brought forward. A sum of £2 916 has been placed to the reserve, and the remainder is carried forward.

Stock Exchange.—The Stock Exchange Committee have ordered the Notting Hill Electric Lighting Company's further issue of 2,200 ordinary shares of £10 each, fully paid, Nos. 10,001 to 12 200, to be quoted in the official list. Applications have been made to the committee to allow the following securities to be quoted in the official list: Aron Electricity Meter, Limited, 125 000 ordinary shares of £1 each, fully paid, Nos. 1 to 125 000 (special application, renewed); the British Columbia Electric Railway Company's further issue of 6,400 non-cumulative 5 per cent. preference shares of £10 each, fully paid; and the Eastern Telegraph Company's further issue of £103,919 3½ per cent. preference stock.

City of London.—In his annual report to the Corporation the electrical engineer of the City (Mr. A. A. Voysey) states that the number of consumers supplied in the City by the City of London Electric Lighting Company last year was 9 855 compared with 8,738 in 1899. In addition to that, up to the beginning of the year about 27 miles of mains had been laid by the Charing Cross and Strand Electricity Supply Corporation in streets in the City, and the equivalent of 3,427 8-c.p. lamps was connected with those mains. The Charing Cross and City Electric Company, which was formed for the purpose of constructing the works necessary under the City of London Electric Lighting Order, 1899, have, he understands, obtained from the Charing Cross and Strand Electricity Supply Corporation the sum of £73,670. 16s. 10d.

London County Council.—At the meeting of the Council on Tuesday next the Bridges Committee will recommend that £6 000 be set aside for supplying and fixing single lifts in the shafts of the Greenwich footway tunnel; that tenders be invited for the erection of the lifts; and that advertisements be issued in the usual journals. Sanction has been given to the St. Pancras Borough Council, under the St. Pancras (Middlesex) Order, 1883, to lay mains along a portion of Charlton-street, Euston-road. Permission has also been granted to the General Post Office to lay a 3in. cast-iron telephone wire pipe across a portion of Tooting Common, subject to the Post Office authorities obtaining any other necessary consents, and to the work being carried out and the ground of the common restored to the satisfaction of the chief officer of the Parks Department.

Islington.—At to-night's meeting of the Borough Council the Lighting Committee will recommend that the laying of mains in Hornsey-road be proceeded with, at a cost of £10,530. They will also submit the following report: "We have had under consideration the difficulties which confront us in connecting consumers in streets where supply mains are laid owing to the restriction contained in Standing Order No. 12 that 'no contract shall be entered into or liability incurred for works proposed to be paid for out of capital until the consent of the sanctioning authority to the borrowing has been obtained.' We recommend that Standing Order No. 12 be altered by the addition of the following words: 'except in the case of low-tension distributors and services required to connect consumers of electricity with the Council's mains which may be laid, after being sanctioned by the Council, as and when authorised by the Lighting Committee.'"

Bolton.—A satisfactory margin of profit is shown by the accounts of the electricity department of the Corporation, which have just been issued, for the year ending March 31 last. The revenue account gives an expenditure of £13,549 (against £6,196 last year), of which £3,036 is represented by wages and £7,751 by fuel; whilst the income amounts to £24 103 (against £12,098 last year), leaving a balance of £10,554. The sale of electricity by meter has produced £12,444, and by tramways £10,107. The capital expenditure has increased from £34 909 in 1896 (the first year of the undertaking) to £145,125 in 1901, whilst the total Board of Trade units generated at the periods named were 149,507 and 2,937,171 respectively. The number of consumers has increased from 65 to 888, and the number of 8 c.p. lamps supplied from 5,100 to 74,395, whilst the price per unit charged has decreased from 5 4d. to 2·22d. The gross profits amount to £10,554, interest on loans figures at £3,815, the sum of £5,881 has been placed to depreciation account, and £857 has been allocated in relief of rates.

Yorkshire Electric Power Bills.—The following have presented petitions in favour of the Yorkshire Electric Power Bill: the Urban District Councils of Ardsley, Bolton-on-Dearne, Burley-in-Wharfedale Calverley, Castleford, Cleckheaton, Darfield, Elland, Guiseley, Holmfirth, Honley, Horsforth, Ilkley, Kirkburton, Kirkheaton, Lepton, Linthwaite, Liversedge, Methley, Netherthong, New Mill, Rawdon, Rothwell, Soothill, Thurstonland, Whitley, Whitwood, and Yeadon; the Rural District Councils of Hunslet, Keighley, Kiveton Park, Leeds (Roundhay and Seacroft), Skipton, and Wharfedale; the Leeds and District Engineering Employers' Association, the West Yorkshire Coalowners' Association, and the ratepayers and inhabitants of Sheffield, Rotherham, and Masborough. The following have withdrawn their petitions against the Bill: the Corporations of Rotherham, Ossett, Pontefract, and Pudsey; and the Urban District Councils of Rawmarsh and Skipton. The following have withdrawn their petitions against the South Yorkshire Electric Power Bill: the Corporations of Rotherham, Ossett, and Pontefract; and the Urban District Councils of Birstall, Rawmarsh, and Skipton.

Woolwich.—At its meeting on Tuesday evening the Woolwich Borough Council decided to offer the Woolwich District Electric Lighting Company, Limited, £80,000 for the purchase of their undertaking which supplies that part of the parish of Woolwich south of the Thames, the Council to take the profits from Dec. 31 last and control the capital of the company, paying 4 per cent. interest on £80,000 from that date until the completion of the purchase, which is to take place at the earliest possible date. The offer is subject to the usual conditions as to the Council's obtaining the necessary powers and loan. The company's directors will recommend the shareholders to accept the offer of £80,000, with £5 000 or thereabouts which is about to be expended on the erection of new plant already ordered. On June 6 the Council will hold a special meeting to consider the advisability of giving notice to the Blackheath and Greenwich District Electric Lighting Company to sell that portion of their undertaking and works as is within the borough—that is to say, in the parish of Eltham. The borough surveyor was instructed to engage a clerk of the works for the buildings to be erected under contract in connection with the electricity and dust destructor works.

Birmingham.—The report of the Electric Supply Committee, to be presented at the next meeting of the City Council, states that the units sold during the year were 3 040,822, realising £55 810. 4s. 2d., as compared with 2,357,806 units, and £45,247. 7s. 6d., for the previous year, being an increase of 28 9 per cent. in units sold, and 23·3 per cent. in money value. The revenue account shows a gross profit for the year of £15,352. 18s. 7d., but had only the usual charges in connection with the generation of electricity and maintenance been debited against it there would have remained a balance of £27,233. 10s. 4d. wherewith to meet the interest and sinking fund charges, which amount to £21,838. 17s. 9d. The exceptional charge against revenue is the cost of altering and improving a portion of the feeder mains and of changing over sections of the department's system from 110 to 220 volts. The first complete year of the working of the system by the department may be considered satisfactory. The works are in excellent order, and operations have been carried on throughout the year without stoppage or serious accident of any kind. The lamp and motor additions during the year on the various circuits, reduced to a 16-c.p. factor, amounted to 11,855, bringing the total number of lamps to the end of the financial year to 78 293, being an increase of 17·8 per cent. The total number of motors now connected amounts to 260, equal to about 710 h.p. The relaying of the older mains in the centre of the city has been completed, and a uniformity of the system has thus been effected. The committee mention that any large extension of the area of supply will necessitate the establishment of new power stations.

Digitized by Google

Shoreditch.—The Borough Council will from July 1 increase the price of current from 4½d. to 5d. per unit, and alter the scale for large consumers (from 2d. to 4d.) to a fixed charge of 4d., and raise the scale for power (from 1½d. to 2d.) to 2d. per unit for all consumers.

Bransksome.—The Urban District Council have granted the request of the National Telephone Company to extend their line of poles at Ringwood-road to Alderney Manor. The Council are conferring with the Bournemouth and Poole Electric Light Company with respect to an electric light supply to the Council's new offices.

Bangor.—At the quarterly meeting of the City Council last week the phenomenal success which had attended the electric light undertaking was referred to. It was stated that a profit of £880 had been made during the first five months. There had been put down as deficit £600, but it should be remembered that £475 of that sum belonged to capital.

Barrow.—The County Council are urging the Local Government Board to hold the enquiry with reference to borrowing powers for electric lighting at the earliest possible date, as certain of the works are extremely urgent—viz., the street and private lighting for the coming winter—and tenders have already been provisionally accepted for about half of the amount.

Tonbridge.—Major F. H. Tulloch held an enquiry on Thursday last week into an application of the Urban District Council to borrow £20,400 as a first instalment towards the cost of the land on which the suggested electric lighting station and works are to be erected. There was a strong opposition to the scheme, and finally the enquiry was adjourned till Friday, the 17th inst., at 10.30.

Morecambe.—The West End Pier Company and the Central Pier Company having asked for a substantial reduction in the present price charged them for electric current, the Council have decided that the present price of 7d. per unit be still charged, but if the annual consumption should amount to £250 for each company, 5d. per unit would be charged for all current consumed above that amount.

Stratford.—The Charing Cross and City Electric Company, Limited, are erecting new works at Stratford. Two sets of counter-current jet condensing plants for 25 000lb. of exhaust steam per hour each, and six circular iron natural-draught cooling towers, each for 75,000 gallons of water per hour (all Balcke's patents), have been ordered from Mr. Arthur Koppel 27, Clement's-lane, E.C.

Northfleet.—The District Council are consulting Messrs. Preece and Cardew with regard to a suggestion which has been made that some scheme should be devised whereby the Council should enter into an arrangement with the Town Council of the borough of Gravesend, which adjoins Northfleet, for taking from Gravesend a supply of electricity during the infancy of their proposed electricity undertaking.

Harrogate.—The Council have decided that where electric motors can be used without in any way interfering with the effective lighting supply of the surrounding neighbourhood, current be supplied at 2d. per unit, providing that the motor be not used for a less average period than six hours per working day, based upon a maximum demand of one third the rated power of the motor.

Shrewsbury.—The Town Council have adopted a report from the Lighting Committee stating that the demand for electric current had increased by 76 per cent. in 12 months, and in two years the profits had been £2,200. New plant was being laid down, and the committee recommended the Council to sanction a further loan of £16,526 for additional cables to meet the ever-increasing demand for the light.

Worcester.—The City Council have appointed the chairman of the Electricity Committee (Mr. Parker) and Mr. Ernest Day to represent the city at the Municipal Electrical Association's convention at Glasgow. The Council have decided to apply for sanction to a loan of £230 for laying an electricity main in the London-road from the end of the existing main to the city boundary at Red Hill.

Lowestoft.—The resident engineer (Mr. Bruce) in his last report states that on April 26 the equivalent of 5 608 8-c.p. lamps (public and private lighting) were connected, representing 103 consumers. Mr. Hawtayne, the consulting electrical engineer, has been asked to furnish particulars of the extension of mains in North-parade, Lyndhurst-road, Corton-road, and Belvedere road, to be included with the application for sanction to the loan of £20,000.

St. Marylebone.—The Council have agreed to a notice from the Metropolitan Electric Supply Company as to laying a 5in. cast-iron pipe along the north side of Crawford-street, from York-place to Gloucester-place, and along Durweston-mews and Spring-mews to new flats; also along the south side of Crawford-street and west side of Spring-street from 128, Crawford-street to present pipe at Montagu mansions, and across Crawford-street at the east side of Spring-street.

Dewsbury.—At the last meeting of the Town Council it was stated that all the protective clauses they asked for in regard to the Yorkshire Electric Power Bill and the South Yorkshire Electric Power Bill, both of which proposed to come into the district, had been obtained. The Yorkshire Company had gone so far as to give up the right of supplying electricity to railway and water companies in the borough, which at first they could not see their way to do.

Hanley.—The electricity mains are to be extended to Trafalgar-street and to Wellington Church, subject to the payment by two consumers of 3½ per cent. on the outlay, until such circumstances arise as will justify a reduction being made. The statement of accounts for the past year's working shows a profit of £3,630. 13s. 8d. on the receipts and working expenses, or revenue account, which sum is insufficient to meet the charges for interest and sinking fund by £641. 9s. 3d.

Southwark.—The wayleave difficulties which have hitherto prevented the provision of a private wire between the infirmary and the Dulwich fire station have been overcome, and the work of erection will now be proceeded with as quickly as practicable. Telephone apparatus of the special make required by the London County Council requirements is to be provided, and as the alteration will enable the Postmaster General to reduce the rental originally agreed to, a fresh agreement is being prepared.

King's Lynn.—The engineer's report states that during the month of April applications for 379 lamps of 8 c.p. or equivalent have been received, making a total of 8 529 lamps of 8 c.p., and that seven new street lamps had been fixed in Wisbech road and Diamond-street. His proposal that a 2in. centrifugal pump and motor combined be fixed in the engine room over the well at a cost of about £70 has been agreed to. This will set at liberty the gas-engine pump tank and pipe, which are to be sold, and much less water will be used.

Wolverhampton.—The annual report of the Wolverhampton Chamber of Commerce states that the local electrical trade has been well supplied with orders during the past year. The works are fully occupied, and the prospects for the present year are good. Electricity is receiving constantly widening application, and promises to be one of the great staple industries of the country. There is room for considerable extension of this business in Wolverhampton, when the advantages of the application of electricity are appreciated.

Newport (Mon.).—The committee of the Corporation charged with the erection and equipment of a station for supplying power for electric trams and for other purposes are firm in their opposition to the new works being placed on the same site as and being at all identified with the existing works, which practically supply light only in Friar street. The new generating station is recommended to be built in Corporation road on a site for which £8,000 has already been paid to Lord Tredegar's trustees. Mr. Parshall, who is advising the Corporation, was invited to be present at the meeting of the Corporation which was called for last Tuesday for the purpose of further discussing the question.

Hammersmith.—The Brook Green works of the Incandescent Electric Lamp Company, Limited, where about 40,000 lamps are turned out every week, were visited last week by the Mayor of Hammersmith and the members of the local Electric Lighting Committee, who after a tour of inspection, expressed delight at all they had seen, both of the company's system of manufacture and of their method of treating their employés, whom they have provided with all the most modern appliances in their work, and for whom they have, in their extension of the premises recently opened, provided an immense dining-hall and clubroom—open to them when the ordinary labours of the day are terminated.

Handsworth.—The Urban District Council's Bill has passed Lord Morley's Committee as an unopposed measure. Under it the Council propose to construct certain lines of tramway and connections to join up with the Wednesbury and West Bromwich, the South Staffordshire, and the Birmingham Suburban and Birmingham Central Tramways systems, and in order to work these they ask powers either to buy electricity or start works for its supply, and also to supply electric light. The cost of this scheme is put at £107,750 and £49,050 for the electric light installation. Prof. Kennedy explained the estimates for the electric installation and laying down of plant, erecting generating station, etc.

Guildford.—The Guildford Electricity Supply Company, Limited, have informed the Town Council, with regard to the paving of footways where permanent paving was to be laid down by the borough authorities, that if the company were not to be charged any part of the cost of permanent paving after they had laid their main in such road they would make special efforts to get their main laid down before the paving was done, but that if they were to be charged for the permanent paving it was not worth their while to do this, as experience showed it was cheaper to them to have the pavement broken up and relaid and pay for the breaking-in in the first instance. The letter is being considered by the Paving Committee.

Malton.—We understand from the *Yorkshire Herald* that no visible practical steps have yet been taken to supply the electric light to Malton, despite the fact that the engineer of the recently-formed electric supply company told the Urban District Council that they would "be there" in July last. As it has been said to take "at least 12 months to get the plant into working order," it may now be assumed that Malton will have to wait much longer than the time originally promised for the light to be in operation. The engineer of the scheme put the initial cost of the installation at £10,000, and the total cost of the supply for the whole district at £40,000. No doubt the new company wish to "see their way" before committing themselves.

St. Albans.—The City Council have adopted a report of the Urban Committee stating that they were of opinion it was desirable that the rights, powers, and liabilities of the Town Council under the electric lighting provisional order should be transferred to a company willing to accept the same, provided proper terms could be arranged, in preference to the Corporation undertaking to carry out the work themselves. The committee further reported that they had considered the offers they had

Digitized by Google

received from the North Metropolitan Electric Power Distribution Company, the British Schuckert Company, and the St. Albans Gas Company, but they were not in a position to make any recommendation with regard thereto at the present time, as they desired to have a personal interview with Mr. Hammond on the subject.

British Electric Works Co.—The British Electric Works Company, Limited, formed in May, 1899, to take over the Stellite Works, Cheston-road, Aston, has decided to go into voluntary liquidation. The Company was floated with a capital of £135,000—£50,000 in cumulative preference shares and £85,000 in ordinary shares—the vendor being Mr. J. Basnett Atherton, who had acquired the concern from R. F. Hall, Limited, for whom the works were erected. Nearly the whole of the capital is held in Liverpool and the district. Mr. Abbot (of Chambers, Wade, and Co., Liverpool) and Mr. Spencer, both chartered accountants, have been appointed liquidators. There is also a petition for compulsory winding up, presented by Messrs. S. Walker and Sons, Limited, of Birmingham, the proceedings on which are still pending.

Walker.—Sanction has been obtained by the Urban District Council to the borrowing of £18,559 for electric lighting and £14,700 for a refuse destructor, the loans to be repayable in 25 years. At the last meeting a letter was read from several manufacturers in Walker, objecting to the erection of the refuse destructor now that the Council had made certain arrangements with the Newcastle Electric Supply Company respecting the supply of electric energy, and intimating that under the circumstances the refuse could be more economically dealt with by sending it to sea. The clerk was directed to state in reply that the whole matter had been fully considered, not only by the Council, but by the Local Government Board, and the latter authority had granted their sanction to the raising of the loan. The Council were of opinion that no good purpose could be served by reopening the matter.

New Malden.—Mr. F. J. Warden-Stevens has submitted to the District Council the following arrangements for a scheme of electric lighting for the district: the Council to apply for a provisional order and obtain the necessary loan for carrying out the work; a responsible company to construct the works and carry on the undertaking, guaranteeing to the Council an interest on the loan and the payment of the sinking fund; the Council to have the option to take over control of the works at the expiration of a period of 14 years. Mr. Warden-Stevens added that the company he had in mind had suggested similar arrangements to a local authority for whom he had acted, and it appeared to him that these would meet the views of the Council, as he believed they were desirous of having some considerable control in the undertaking themselves. The Council have asked for further particulars.

Hull.—Colonel W. Langton Coke has held an enquiry into the application of the Corporation to borrow £17,000 for purposes of electric lighting. In July, 1897, the Corporation applied for £40,000 for the purpose of laying down the installation on the high-tension system in the Sculcoates-lane district. The Corporation erected a large station in Sculcoates-lane, and put down generating plant—as they had in the first instance in Dagger-lane—which was for the Old Town. The application of last week provides £9,575 for high-tension feeder mains from the Sculcoates-lane works to the Dagger-lane works. The other items are for new distributing mains and for a new plant from the Sculcoates station, including a new steam dynamo and switchboard, and lamps for the new streets, which the Corporation were constructing, and the purchase of additional land adjoining the Sculcoates-lane works. Mr. Barnard, the electrical engineer to the Corporation, submitted the plans and explained the extensions.

Luton.—The Council have decided to charge 6d. per unit for the first 100 hours, and 3d. per unit afterwards. They have invited Lord Kelvin to perform the opening ceremony in connection with the electricity works on June 24. The battery-room is nearly completed, the engines are fixed and the boilers in position. Mr. W. H. Cooke, of 35, Crawley-road, Luton, has been appointed resident electrical engineer; he will be allowed the privilege of having one pupil. The town clerk's estimate of the receipts and expenditure of the Electric Lighting Committee for the period ending March 31, 1902, shows a total expenditure of £2,174; the estimated income from sale of current and rent of meters is put at £853. 15s.; leaving a deficiency to be met by the general district rate of £1,321. 3s. 6d. The Free Wiring Company has been informed that the committee have reduced their maximum charge to 6d. per unit, the minimum 3d. per unit, in order to ascertain whether they would submit terms and conditions as to free wiring of premises within the borough.

Brierfield.—The Urban District Council have received from the town clerk of Burnley a letter on the electricity question to the following effect: (1) That it is unpracticable to give a satisfactory supply of energy in bulk for lighting and traction purposes from same cable. (2) For lighting purposes they were willing to put down the plant and supply Council at the rate of 5d. a unit for a maximum consumption of 30,000 units per annum, the latter quantity to be paid for whether consumed or not. If the consumption largely exceeds 30,000 units per year they would revise the price. (3) They were not prepared to quote a price for the supply of energy in bulk as the cost would be prohibitive. "Mr. Birkett's scheme for supplying electricity was," says the letter. "to transmit energy at 2,400 volts to a sub-station in the centre of Brierfield where the voltage would be transformed to 230 volts. Brierfield would receive this energy at the lower voltage and distribute it at their own cost." The Council, however, have decided not to consider the offer.

Whitehaven.—The Council have made arrangements with the Earl of Lonsdale for the use of a portion of the shipyard for the purpose of carrying on the necessary work in connection with the electric lighting works. The electrical engineer has been authorised to purchase a wheelbarrow and two separate battery cells for use at the station. The question of the committee joining the Municipal Electrical Association has been deferred for 12 months. Notice is to be given to the consumers and tradesmen of the intention of the Council to double the pressure on the mains, and application is to be made to the Board of Trade for their consent. At the last meeting of the Harbour Commissioners the amount of the bill for electric lighting was commented upon, and it was said the arrangement between the Harbour Commissioners and the Corporation was to give the Harbour Commissioners certain lamps, and if the Harbour Commissioners thought they could do without a lot of those lamps they might ask the Electric Lighting Committee to put in switches at various points, so that the harbour officials could switch off any lamps not required at the time.

Warrington.—Application is to be made for sanction to the borrowing of a further sum of £15,000 for extensions of the electric lighting station. The total receipts for the quarter ended March 31 have amounted to £457. 4s. 5d. and the expenditure to £417. 1s. 9d., so that on the revenue account there is a balance of £40. 2s. 8d. to credit. In addition to this, there has been a certain amount of expenditure in connection with the lighting of the street lamps. Altogether, the account will show on working expenses account a balance to credit of £100. Considering the circumstances under which the committee have carried on the work during the quarter when they only had two or three customers at the commencement and the majority only towards the end of the quarter, a consumption of 21,000 units may be considered fairly satisfactory. Mr. Grimsdale, the electrical engineer, in his last report states that no fewer than 8,607 8-c.p. lamps have been actually connected, that applications have been received equal to 857 more, and a further 639 lamps are to be put on as soon as arrangements can be completed for the purpose; so that there will be no less than 10,103 8-c.p. lamps within the next month or two. In the report originally submitted, Mr. Preece based his estimate of the probable income and expenditure upon 10,000 8-c.p. lamps. The Council are already supplying a quantity in excess of this estimate.

Jarrow.—Messrs. Palmer's Shipbuilding and Iron Company, Jarrow, have just had completed for them a very fine electric driving plant, the object of which is to work the whole of the machinery in the engineering and shipyard departments, and which will enable the company to do away with a considerable number of boilers, etc., thus effecting a great saving, and will undoubtedly prove a very powerful addition to their present great resources for executing their work with dispatch and cheapness. Messrs. Clarke, Chapman, and Co., in conjunction with the Westinghouse Company, have carried out the electrical part of the work. The three-phase alternating-current system of 440 volts has been adopted. A large number of motors has been placed throughout the works to drive the various section of the shops and separate machines. The current is generated in a large central power station, placed near the riverside, in which are two complete sets of plant, each having a generator of a normal output of 750 kw. The driving power is obtained from two sets of vertical triple-expansion engines, with three cranks, of marine type, each provided with a heavy flywheel, this part of the work having been done by Palmer's Company themselves. The generators are driven directly, with only the flywheel and shaft intervening between them and the engines. The normal revolutions are 164 per minute. Steam is supplied by four Lancashire boilers, fitted with an economiser and with induced draught. Altogether the plant is probably the largest and most complete of its kind so far that has been fitted to any works in the United Kingdom.—*Jarrow Express.*

Sheffield.—An instance of the enterprise of the electric light department of the Corporation (says the *Sheffield Daily Telegraph*) is furnished by the installation of the light in the large hall of the corn exchange, where the fruit and flower market is now held. The town hall has, of course, been lighted by electricity since its opening, but the corn exchange is the first important public building in which this illuminant has been fitted since the works in Commercial-street were taken over by the municipal body. Mr. Fedden, the general manager, hopes that the departure now made will prove the first of a series, and that before long electricity will be installed at the other markets and also at the baths. The substitution of electricity for gas at the corn exchange will be advantageous, apart from the question of superior illumination, as the atmosphere will be less heated, and more favourable to the flowers and fruit stocked in the hall. The size of this room is 150ft. by 75ft., and for lighting it 15 enclosed arc lamps are suspended from the roof, and are 13ft. 6in. from the floor. Each lamp lights a space of 750 square feet. They are of the Davy type, with single globe and reflector. Each takes about 6½ amperes of current, and gives approximately 1,000 c.p. They will burn for 50 hours with once carboning. This is an advantage over the ordinary arc lamps, which only burn about eight hours, and which, if used at the corn exchange, would need carboning in the winter time every day. Once a week will suffice in the case of the new lamps, so that the cost of carboning is reduced to one-sixth. The whole of the lamps are controlled from one position, but each switch governs two lights. The work of installation has been carried out during the last three weeks

Digitized by Google

by the wiring and fittings department, under the supervision of Mr. J. W. Barnes. The light was switched on for the first time on the 11th inst.

PROVISIONAL PATENTS, 1901.

MAY 6.

9311. Improved fuse head for electric blasting. Frederick Render, 6, Bank-street, Manchester.

9326. Improvements in X-ray tubes. George Henry Smith, 37, Daniel-street, Cathays, Cardiff.

9330. A device for quickly connecting the trolley wheel of electrically-driven tramcars or other vehicles with the overhead wire supplying the power, and which is usable in any position of the trolley arm. Edward John Simmonds, 3, Wesley-villas, Hyde Park-road, Mutley, Plymouth.

9350. Improvements in and relating to electric furnaces for heating or reheating objects to a predetermined degree. Adrien Grobet, 11, Southampton-buildings, Chancery-lane, London.

9384. Improvements in electric arc lamps. Walter Claude Johnson and William Beedie Esson, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

9388. Improvements in electric arc lamps. Helios-Upton Company and Thomas Spencer, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 7.

9405. The training of guns by electric motors without the use of resistances. Harry Egerton Wimperis, Gonville and Caius College, Cambridge.

9445. Improvements in the rectification of high-tension alternating electric currents. Russell Stuart Wright, 52, Cromwell-avenue, Highgate, London.

9502. Improvements in telephone transmitters. William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Charlton E. Yocom, United States.) (Complete specification.)

9512. Improvements in solenoid and other electric coils. John Allen Heany, Norfolk House, Victoria-embankment, London. (Complete specification.)

9527. Improvements in connection with electrical fuses. James Yate Johnson, 47, Lincoln s-inn-fields London. (The D. and W. Fuse Company, United States.) (Complete specification.)

MAY 8.

9532. Improvements in motor-starting switches. Frederick Joseph Arundel Matthews, Revidge, Bowden-lane, Marple, Cheshire.

9547. Improvements in electric stop motions of drawing frames. Thomas Chadwick, Penny Bank-chambers, Halifax.

9574. An instrument for the testing of the magnetic qualities of materials in bulk. Charles Vickery Drysdale, Clairville, Hadley-road, New Barnet, London.

9586. An invention for extending the present range of wireless telegraphy. Florence Lacon and Arthur Foster, 11, Great Cumberland-place, London.

9593. An improved electric switch for starting motors or like purposes. Siemens Bros. and Co., Limited, and Maurice Hird, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

9605. Instantaneous device for securing telegraph, telephone, or other wires. Quelez Austen, 64, Grange-road, Hove, Sussex.

9610. Improvements in electrical exercising machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Albert Williamson Courtney, United States.) (Complete specification.)

9611. Improvements in trolley heads for use in connection with the overhead system of electric traction. Anthony Metcalfe, 46, Lincoln's-inn-fields, London.

9616. Improvements in and relating to electrical time switches. Wilhelm Rausch, 60, Queen Victoria-street, London. (Complete specification.)

MAY 9.

9619. A new or improved method of conveying electric current, a new or improved apparatus in connection therewith. John Iron, Harbour House, Dover.

9651. An improved method for the protection of overhead systems of transmission of electric currents. Cecil John Reginald Le Mesurier, 19, Perrymead-street, Fulham, London.

9674. Improvements in electric arc lamps. The Jandus Arc Lamp and Electric Company, Limited, Adrian Denman Jones, and Bernard Mervyn Drake, Hartham Works, Hartham-road, Holloway, London.

9675. Improvements in the regulating mechanism for electric arc lamps. The Jandus Arc Lamp and Electric Company, Limited, and Adrian Denman Jones, Hartham Works, Hartham-road, Holloway, London.

9676. An improved electric smelting process and apparatus to be used therein. The British Aluminium Company, Limited, 6, Bream's-buildings, Southampton-buildings, Chancery-lane, London. (Alfred Hutchinson Cowles, United States.) (Complete specification.)

9692. Improvements in underground systems for electric traction railways and the like. Carl Haggenmiller, 6, Lord-street, Liverpool.

9697. Improvements in or connected with wireless and other telegraphic signalling. Jagadis Chunder Bose and Sara Chapman Bull, 53, Chancery-lane, London.

MAY 10.

9718. Improvements in electrical heating apparatus. August Eckstein and Charles Herbert Archer, Peel Works, Adelphi, Salford, Manchester.

9731. Improvements in the method of lighting oil and other lamps by electricity. William Patterson, 5, Lord-street, Lower Broughton, Manchester.

9740. An improved ceiling switch. Augustus Reckenzaun, 165, Queen Victoria-street, London.

9745. An improvement in or relating to electric current circuit breakers. Ernest Francis Moy and Percy Henry Bastie, 37, Essex-street, Strand, London.

9769. Improvements in current collecters or contact-shoes for electric railways. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (McElroy-Grunow Electric Railway System, United States.) (Complete specification.)

9770. Improvements in electrical sparking devices for firing the charges in internal-combustion engines, and for similar purposes. Alfred Charles Brown, 129, Algernon-road, Lewisham, London.

MAY 11.

9781. An improved insulator for use with bracket suspensions of overhead trolley systems, and the like. Robert Cornelius Quin and John Berry Smith, 5, Blakiston-street East, Fleetwood.

9785. Improvements in reversing apparatus for electrical devices. Robert Joseph Hughes and Alexander Bruce Shaw, Fife House, Kingston-on-Thames. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Oct. 13, 1900, being date of application in United States.)

9801. Improvements in electric telegraphy. Sidney George Brown, 9, Putney hill, Putney, London.

9812. An improvement in controllers for electric motors for lifts and other purposes. John Bush and Matthew Thomas Medway, 175, Shardeloes-road, New Cross, London.

9829. Improvements in automatic electric circuit breakers. The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, Bush lane House, Cannon-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on June 1.

1900.

6312. Apparatus for the production of soda and chlorine by the electrolysis of chloride of sodium, also applicable for the production of potassium, sodium, aluminium, or other metals of the same class. Cohu and Geisenberger.

8315. Electric switches. Jones.

9633. Strap coils for electrical machines. Mallett. (Date applied for under International Convention, Oct. 7, 1900.)

10639. Electric controllers. Thompson. (Fraser Electric Elevator Company.)

12466. Construction of rail bonds for electric railways and mode of applying same. Hardingham. (Felten und Guilleaume Carlswerke Actiengesellschaft.)

13951. Electric muffles or furnaces. Weiss.

1901.

1611. Apparatus for testing electric meters. Del Nero and Camino.

1339. Electric trolleys. Allison. (Pemberthy Injector Company.)

1488. Electric measuring instruments. Brooker and Russell.

1660. Electric tramways on a sectional conductor closed-conduit system. Hore, Rydl, and Vsětecka.

2570. Electric signalling apparatus. Mildon.

4096. Railway electric signalling apparatus. Hume.

4767. Cable for supplying the electric current to electrically-driven ploughs, and for like purposes. Meissner.

7113. Apparatus for rectifying alternating electric currents. British Thomson Houston Company, Limited. (Green.)

7114. Electric regulators. British Thomson-Houston Company, Limited. (Everest.)

7224. Apparatus employed for covering telegraph cables and wires with lead or other metallic substance for electric purposes, or for manufacturing metallic pipes or tubes or like uses. Claremont and Stratton.

Digitized by Google

7338. Electric furnaces. Schneider.

7497. Contact boxes for the distribution of electricity. Chruvellier. (Date applied for under International Convention, Nov. 21, 1900.)

NOTES.

The German Visit.—We understand that the preliminary arrangements for the Institution visit to Germany are now almost complete, and that the date of departure—namely, Saturday evening, June 22—remains unchanged. The circulars giving the completed programme will, we are informed, be issued immediately after Whitsuntide.

New Book.—Mr. J. H. Rider, the recently appointed chief electrical engineer to the London County Council, has been engaged for some time on a treatise on "Electric Traction," which he is writing for Messrs. Whittaker and Co. It is to be published, we understand, in the autumn, and will treat very fully on the different systems of electric tramways.

A Novel Electric Lamp.—A novel and most useful contrivance of an electric lamp for use especially in reading meters is the invention of Mr. Oster, of Urdingden. As usual in this class of lamp, the accumulator is carried in the pocket, but the lamp in question is so made as to allow of its being carried in the mouth. A squeeze with the teeth sets it in action, with the obvious advantage that both hands are left entirely free.

National Electrical Contractors' Association.—We are asked to state that a meeting will be held at 46, Queen Victoria-street, E.C, on Tuesday, the 28th inst., at 2 p.m, for the purpose of forming the National Electrical Contractors' Association, already referred to in these columns. The attendance of members of electrical contractors' associations already formed, and of electrical contractors disposed to identify themselves with the movement, is cordially invited.

The Electro-Harmonic Society. — The annual general meeting of the above society will be held on Wednesday, the 29th inst., at the Institution of Electrical Engineers, 28, Victoria-street, Westminster. We understand that during the past season 80 gentlemen have been elected and placed on the register of members of the society, and 19 old members have resigned. In the same period the society has lost three members by death, while four have been struck off the register for non-payment of subscriptions. The membership roll now includes 332 names.

The Pacific Cable.—We regret to note that the arrangement made between the Government of New South Wales and the Eastern Extension Telegraph Company, which was adversely criticised in our columns some time ago, is having an injurious effect on the prospects of the scheme for an all-British cable across the Pacific. The last instance of this is the determination on the part of the Canadian Government to hold back the Pacific Cable Bill until it has been decided as to what will be the actual effect of the arrangement above mentioned with the Eastern Extension Telegraph Company.

Institution of Junior Engineers.—On Monday evening last the members of this institution paid a visit to the works of the Renewable Electric Lamp Company at Brunswick-place, City-road, E.C. We are informed that, in addition to the renewing of old lamps by the introduction of a new filament, the company are manufacturers of incandescent lamps, the filament being prepared in a special way. Its consumption of current claimed is as low as 2·7 watts per candle-power, and it is guaranteed to burn 1,000 hours. In the renewal process the bulb is reopened, the old filament is detached, and a new one inserted, thus avoiding the wastage of the bulb, the cap, the platinum, leading-in wires, etc. The visit concluded with a vote of thanks to the managing director of the company, Mr. H. E. Kershaw.

National Telephone Dinner.—The eighth annual dinner of the staff of the National Telephone Company took place at the Trocadero Restaurant on Friday last. Mr. W. E L. Gaine, the general manager of the company, presided, and as showing the position of the company he gave the following figures in the course of the evening: Last year they had 968 exchanges, while this year they have 999, and "notwithstanding all the threats of competition and suggestions of inefficiency," they now have 205,000 subscribers, compared with only 176,000 in 1900; while, although the increase in inland telegrams during the 12 months was 2·88 per head, the increase in telephonic messages was 15·3, the total of the former being 90,000,000, while the total of the latter was 712,000,000. The company was also addressed by Sir Cuthbert Quilter, M P., and Lord Kelvin.

Explosives on the Line.—What was at first regarded as a serious attempt to disorganise the Corporation electric tramcar service occurred last week at Liverpool, when two American cattlemen were arrested on a charge of placing explosives on the tramlines. Reports were heard in the centre of the city on two successive evenings, and on investigation it was found that revolver cartridges had been placed on the tramlines and exploded by the cars. On the second occasion a young man was struck in the cheek by a bullet $\frac{3}{4}$in. in length. When charged with wilful intent to endanger life and property, one of the cattlemen admitted having placed cartridges on the track, but pleaded that he "only wanted to hear them go off, and had no idea that there was any danger." This explanation was evidently accepted by the magistrate, who took a most lenient view of the case, imposing a fine of 40s. and costs on the first man and discharging the other.

Municipal Supply in Bulk.—The conference which was held on the 16th inst. between the representatives of the various local authorities in Greater London and the London County Council was kept private. In spite of that, the actual resolutions, or, rather, the gist of them, have leaked out. We gather from this that the conference reaffirmed a resolution which was passed at a similar gathering some three years ago in favour of the London County Council supplying electricity in bulk to local authorities. The conference further decided by resolution that the Council should be asked to draft a suitable Bill in order to obtain powers to this end. It remains to be seen how this Bill can be drafted in such a way as to avoid interfering with present interests, and also as to what proposals the London County Council will incorporate in the same as to joint control of the stations which would be used for supplying local authorities in bulk.

Pole-Setting in Swampy Ground.—The difficulties of pole-setting vary with the nature of the ground in which it is required to place the poles For instance, electrically-driven pumps are now used for draining the low land around New Orleans, and these are located at different pumping stations, which are supplied with current from a large central generating station established for the purpose. The difficulty here was that the New Orleans soil tends to rot timber very rapidly, and some method had to be devised for preserving the poles underground. The plan adopted was to first put a box of about 1in. larger dimensions than the pole in a concrete setting. Then, after the base of the pole had been placed in the hole in the concrete left on the removal of the box, sand was poured in around it, which effectually preserved it from the effects of the swampy soil. In the case of very soft ground it was found necessary to fasten the poles to piles

Digitized by Google

driven 26ft. below the surface in order to preserve them upright.

Niagara Power.—We gather from a note in one of our American contemporaries that the Niagara Falls Power Company intend to proceed at once with the development of the power of the Horseshoe Fall, the present plan being to obtain some 35,000 h.p. Of this about one-third is required to operate an industrial establishment in the vicinity, while another third is to be transmitted to Toronto. The remaining third will be held in reserve for the use of the company itself on the American side of the river. According to the present intention, the two power-houses of the company in Niagara Falls, New York, and the new power-house on the Canadian side, will be connected. The development of the power will necessitate the construction of an inlet canal from Cedar Island to the power-house site, where the wheel pit will be sunk, a tunnel carrying the water to the lower river below the Horseshoe Fall. This pit and tunnel, it is said, will suffice for turbines having a capacity of 100,000 h.p.

Mechanical Engineers' Conversazione.—The conversazione given by the Institution of Mechanical Engineers as the closing function of the session passed off last Friday with complete success. The large company, numbering over 800 ladies and gentlemen, were received in the great hall of the institution building by the President and Mrs. Maw. Among those present were the Earl of Rosse, Sir J. Aird, M.P., Sir Edward Carbutt, Sir W. White, Dr. Alexander Kennedy, the Hon. C. S. Rolls, Sir Hiram Maxim, Sir Frederick Bramwell, Sir Benjamin Baker, Prof. Henry Robinson, Mr. J. A. Thornycroft, Mr. Charles Hawksley, Mr. J. A. Aspinall, Mr. W. H. M. Christie, and many other gentlemen interested in different branches of science. The band of the Coldstream Guards gave various selections in the library, and a programme of vocal music, under the conductorship of Mr. Alfred Smythson, was also provided. An interesting feature of the programme for the entertainment of the visitors was an exhibition of photographic views of the great Nile dam by Sir Benjamin Baker.

Royal Meteorological Society.—The monthly meeting of the Royal Meteorological Society was held on the 15th inst., when Mr. W. Marriott gave an account of the bequest to the society by the late Mr. G. J. Symons, F.R.S., who was the founder of the British rainfall organisation and a most distinguished meteorologist. By his will Mr. Symons bequeathed to the society his cross of the Legion of Honour, the gold Albert medal awarded to him by the Society of Arts, the testimonial album presented to him in 1879 by the Fellows of this society and the sum of £200, as well as such of his books, pamphlets, maps, and photographs of which there was no copy in the society's library. Mr. Marriott stated that from Mr. Symons's valuable collection he had selected for the society over 5,000 books and pamphlets, and about 900 photographs. A large number of the books were old and rare works, 750 bearing dates previous to 1800, while eight were as early as the fifteenth century. By this noble bequest, it is claimed, the Royal Meteorological Society now possesses the most complete and extensive meteorological library in existence.

Water Power and Irrigation.—Irrigation combined with electric utilisation of water power is the latest problem to which American engineers have been devoting their attention, with the result, we are told, that the water in falling from the high levels of the mountains to fulfil its work of irrigation on the plains has been made to pass through turbine wheels and thus generate power. The *Electrical Review* of New York, editorially commenting on the question, says that California, for example, has districts where such a system of utilising the mountain torrents for both purposes seems to promise an actual production of wealth greater than could be measured by all the gold ever dug out of the soil of that State. It is inevitable that manufacturing industries of great importance will sooner or later spring up around the water powers of that region, while the water itself having done its work in turning the dynamo, will furnish food for the great influx of population that such manufacturing would entail, as well as being applied to irrigation purposes. Up to very recently, the potential energy of the water applied solely to this latter need in America has been absolutely wasted.

Mercardier Telegraphy.—We gather from a note in one of our daily contemporaries that a new system of telegraphy is being experimented with at the Post Office. From the details given of the new system, it would seem that it is the one described by Mr. Gavey in his paper before the Institution in November last as devised by Mr. E. Mercardier. By this multiple telegraph system it is claimed that 24 messages can be sent simultaneously over one circuit, 12 in each direction. The device is based on the harmonic system. A number of vibrating reeds are used, each differing from the rest by a certain defined period of vibration. These, when used to send signals to the line, cause a complicated system of vibrations to be set up in the currents transmitted. The line current is then analysed at the receiving end of the line by the series of receiving reeds or telephones only responding to the notes to which they have been tuned. With the Mercardier system Morse characters alone can be transmitted up to the present. It is stated that the inventor has been so successful with the tuning of the various parts, that satisfactory results have been obtained on a circuit between Paris and Bordeaux. A complete metallic surface is, however, required for satisfactory working.

Light Railways.—A parliamentary paper has just been issued embodying the proceedings of the Board of Trade under the Light Railways Act and of the Light Railway Commissioners up to Dec. 31, 1900. We gather from the report submitted by the late Sir Courtenay Boyle on behalf of the Board of Trade, that on Dec. 31, 1899, there were 18 orders before the Board for consideration. Out of these 13 were confirmed during the year under review, while the remaining five were held over for various reasons, one of them having since been confirmed. Again, out of 40 fresh orders submitted by the Light Railway Commissioners, 16 were confirmed by the Board of Trade. The remaining orders, 24 in number, were still under consideration on Dec. 31 last, but of these 10 have since been confirmed. The report also refers to six orders in respect of which the Treasury have conditionally agreed to make advances. The report of the Light Railway Commissioners states that 56 applications for orders to authorise light railways were made in the year 1896-97, 65 in the year 1897-98, 94 in the year 1898-99, 67 in the year 1899-1900, and 27 in the month of November, 1900. In respect of 133 applications the Commissioners have now submitted 126 orders to the Board of Trade for confirmation.

Electromagnetism as a Therapeutic.—We notice in the *Electrical Review* of New York the description of an apparatus devised by a Mr. John Barry, of that city, which is said to have given relief in all cases of rheumatism and certain kindred diseases. The device in question consists of a large hollow solenoid which is enclosed in a metallic cover, the length of which can be varied by removing segments at will. The length of the apparatus is then so varied as to just cover any limb which has to be treated. Alternating currents are then put through

Digitized by Google

the winding of the solenoid of such a strength as to cause a considerable alternating magnetic field in the space occupied by the limb under treatment. We should like to have seen some information as to the actual strength of field obtained, because obviously this field has to be set up in a material whose permeability is practically unity. According to the explanation of the inventor, the action is to cause alternating local currents which do not have any electrolytic effects, but which stimulate the blood and improve the circulation. We can quite realise that some such effects would take place, and it is only a matter of experiment as to how far they are successful in overcoming disease. Careful measurements by a qualified electrical engineer under the supervision of a medical man would be of great value in ascertaining exactly what effects do take place.

Sychronising Alternating-Current Machines.—When synchronising an alternator to bring it into parallel with other alternators working on load, it is exceedingly important that the connection should be made absolutely at the right instant in order to avoid throwing additional load on the machines already working on the circuit, which may be heavily loaded. In fact, in certain of the London stations, when dealing with a sudden fog, there is no time frequently for new machines to be synchronised before they are switched in. In such cases damage is sometimes done by the haphazard way in which the new machine is thrown into circuit. As an indicating apparatus as to what is the right period to switch in, a voltmeter is more reliable than the usually employed incandescent lamp, because the eye is not sufficiently sensitive to variations in voltage when looking at a lamp the brilliancy of which is varied rather rapidly. Even with a voltmeter there is a need for an apparatus which would automatically close the switch at the right instant. The nearest approach to this we know of is a device working in the exactly opposite direction, in that it cuts the incoming alternator off again if the current exceeds a predetermined limit immediately after the main switch has been closed. We believe that Mr. Andrews, of Hastings, was the first to introduce these maximum and non-return current cut-outs for alternators in this country, but there are now other types being introduced which have the same object.

A Frequency Changer.—With the use of abnormally low frequencies for three-phase transmission work, the need arises for a frequency changer in order that the electric lighting done from the power mains may be of a satisfactory nature. Opinions differ as to the lowest frequency which can be used both for lighting and power, but there is often an advantage in power work in employing a frequency below that at which satisfactory results can be obtained with arc or incandescent lamps. We have recently seen in the columns of the *American Electrician* the description of a rotary frequency changer manufactured by the Stanley Electric Manufacturing Company, of Pittsfield, Mass. This consists practically of an inductor alternator having a single exciting coil, which is fixed in between the two cores which carry the armature coils. The winding on one of these cores acts as a generator circuit, receiving a current at a frequency of 25. The winding of the other armature core is so arranged as to give a frequency of 50 complete periods per second. In order that this may be done, the laminated projections on the rotor which come opposite the first or generator armature core are of twice the size and only half the number of those opposite the motor core. It will be seen from the above description that the machine has several advantages as a frequency changer, in that one exciting coil suffices for what is practically a double machine. Naturally, however, the change in frequency is invariable. We understand that the machine is run up to speed by a small induction motor.

Frequency Converters.—We notice in the *Electrical World* a description by Mr. A. S. McAllister of a frequency converter, in which the frequency of the secondary current can be made practically anything by means of slight alterations in the original design. The principle on which the author proposes to work is that of using an ordinary induction motor as a frequency changer. It is known, for instance, that if the rotor of an induction motor is fixed, it has the current induced in it, the frequency of which is equal to that of the current supplied to the stator. Again, if the induction motor is allowed to run up the speed, the frequency in the rotor becomes less and less. If, now, the secondary is driven by independent means at any fixed speed, the frequency obtained in it by the combination of its speed and of the speed of the revolving field can be made anything at pleasure. The author suggests for the driving a synchronous motor, so that a constant frequency would be obtained in this secondary. By means of analysis he then shows that the actual dimensions of the machines will be considerably less than if the whole of the current required was actually converted. In fact, the power which has to be supplied by the frequency converter, bears to the total output the ratio of the primary frequency to that of the secondary. The rest of the power is then supplied by the synchronous motor. For instance, if a lighting load of 60 kw. has to be taken from a power circuit the frequency of which is only 25, and assuming that the frequency of the lighting circuit has to be 60, then the capacity of the frequency converter will have to be 25 kw., and that of the synchronous motor 35 kw. This idea of Mr. McAllister seems to have in it the elements of success.

Tramway Comparisons.—In its issue for May the *Street Railway Journal* has an editorial note comparing the figures obtained from the tramways in Great Britain and Ireland for the year ended June 30, 1900, with those of various street railways in operation in America. Taking the gross receipts from operation, these in the case of Great Britain and Ireland amount to £5,282,240, and it is shown that the gross receipts of two companies in one city in America, the Metropolitan Street Railway Company of New York and the Brooklyn Rapid Transit Company, nearly equal our results, the total being £5,205,128. Again, the gross receipts of the Massachusetts companies amounted to £4,277,528, and it is pointed out that these companies, with lower gross receipts, paid just about twice as much in taxes as the English companies, and that the roads in Greater New York paid about 2½ times as much in taxes. Of course, this is easily explained away by the fact that the taxes paid by the street railways in the States are very much greater than in the United Kingdom, so that a comparison of this sort conveys no reliable information of value at all when making a comparison. We are rather amused to find that at the end of this article the total payments on account of injuries and damages payable by the companies are given in comparison. If this is to be taken as a reliable basis of comparison as to the relative importance of the street railway or tramway systems on either side of the Atlantic, we in this country certainly take a back place. For instance, while Massachusetts has been held liable for £118,501 in respect of these matters, we in this country have only paid £38,538 during the same period. We agree that gross receipts, and to some extent taxes, may be taken as a fair basis of comparison, but it is absurd to suggest that the compensatory liabilities in respect of accidents, etc., have any bearing whatever on the relative positions of the tramway industry in the two

Digitized by Google

countries. It would appear to us that the low figure laid to our account as compared with the States is rather a matter for congratulation than otherwise.

Electrically-Controlled Bulkhead Doors.—Mr. George W. Walsh has an article in the *American Electrician* on this subject which embodies several interesting points. The repeated failures of bulkhead doors to close promptly enough to save the ship have caused dissatisfaction and anxiety in many quarters. Both the hydraulic and pneumatic methods of controlling these doors have proved at least uncertain enough to involve an element of danger. Electricity, on the other hand, is peculiarly well adapted to the performance of this work on a steamer. One great thing in its favour, the author points out, is that a sudden and great power can be exerted at a critical moment, exceeding often by far the normal rated power of the apparatus. Owing to the fact that electricity is used so generally on shipboard now for a great variety of purposes, a new auxiliary source of power does not have to be installed to control the bulkhead doors in an emergency. For nearly a year now there have been in operation electrically-controlled bulkhead doors on the United States cruiser "Atlanta." The apparatus used was devised by Naval Constructor Francis T. Bowles, of the Brooklyn Navy Yard, and a model of it was placed on view in the war material building at the Paris Exhibition. According to Mr. Walsh, this apparatus has proved so successful that the Navy Department of the United States has decided to equip all future warships with the electrical mechanism, while many of the warships now in service will gradually be changed also in this respect. The "St. Paul" and other ocean merchant steamers have also adopted the electric bulkhead door. Among the many unique features of the apparatus, it is so wired that the officer in charge can operate it from the bridge, and by pushing a button he can tell at any moment the condition of the door. A small lamp near the button indicates whether or not the door is in good working order, the current being automatically cut off when the door is closed, and so darkening the lamp. One great advantage of the invention is that one or a dozen doors may be closed simultaneously or in rapid succession. In cases of emergency there is provision made for local control of the apparatus between decks in addition to the control from the bridge.

The Newport Tramways.—We have received a copy of the *South Wales Argus* for May 15, in which there is an amusing *résumé* by the editor of the debates in the Newport Town Council over the acceptances of the contracts for the tramway power station. According to the editor's account, the fight was a three-cornered one. The first party advocated that the power station, which is to be equipped under the supervision of Mr. Horace F. Parshall, should be used to supply not only the tramways, but also a certain amount of power for other purposes—perhaps some lighting, from what we can gather. The next party advocated the use of electric tramways, but were not in favour of municipal control. The third party strongly supported the present electricity works, and advocated that the supply for the tramways should be taken from plant erected either in the station or in extensions of it. It will be remembered that the lighting station, which was one of the first equipped by Mr. Robert Hammond as consulting engineer, supplies on the single-phase alternating-current system, whereas the tramways require continuous current, and the same is advocated for the supply of motors, and also for lighting in the central portions of the town. The end of the debate seems to have been exciting, as personal remarks were made by various members of the Town Council. We think that the Council were not well advised, however, when they called in the resident engineer of their electric lighting works and asked him to give his opinion as to the position of the tramway works. It is not right to expect two electrical engineers to argue out differences of opinion for the edification of any town council. The more dignified course, having called in outside advice, is to adhere to the advice given, which has practically been done in this instance, except that a needless amount of heat was generated by the discussions of details in public. It was incidentally mentioned at the meeting in question that Mr. Robert Hammond had resigned his position as consulting engineer to the Council on electric lighting matters. The most amusing part of our contemporary's report is the editorial comparison of the eloquence of the two experts who have advised the Council on their electrical undertakings.

London County Council Tramways.—The agenda of the London County Council for this week contains a report of the Highways Committee, which is dated May 16, concerning the proposed reconstruction for electric traction of the considerable further portion of the London County Council tramways. The details as to which of the lines are next to be started will be found in a note elsewhere in this issue, and these lengths involve the equivalent of some 13½ miles of single track. With respect to the equipment of these lines, the Highways Committee suggest an entirely different procedure to that adopted for the first three sections of the tramways now under reconstruction. Acting on the advice of their chief engineer, the committee propose to take full advantage of the experience of the various firms of contractors who are used to executing such work. The specifications on which tenders are to be invited are therefore to be drawn up in such a way as not to bind the parties tendering to any details of construction. For instance, instead of a particular design of yoke and insulator being selected on which all parties have to tender, the actual design will be left to those who offer to supply and equip the same. If it is the desire of the committee to proceed quickly, we think that their procedure is one which will have advantages. But the question arises as to how far it is advisable in the long run to let piecemeal the contracts for the equipment of small lengths of a large system of tramways. For instance, as things now stand with the London County Council, the first eight miles or so of tramway will be equipped with a conduit designed by Prof. A. B. W. Kennedy, and with the one kind of insulator. The next lengths, according to the agenda now before us, are likely to be equipped by A. B. and Co., with another type of conduit and insulator. There are certain dimensions, of course, which have to be the same in each. Again, when the third section of the line is equipped most likely another firm will have the contract. We should then get some 20 miles of track in various parts of South London, all contiguous, and each equipped with a different system. Of course, the difference would mainly lie in the means for supporting the insulated conductors, and the County Council would get valuable experience. It is questionable, however, how far this valuable experience—which would be of the nature of a good knowledge of how not to do things—would make up for the trouble arising out of the want of uniformity.

Two versus Four-Motor Cars.—At the meeting of the New England Railway Club at the end of February last, two papers were read on the advantages of cars equipped with two motors as compared with those of cars having four motors—*i.e.*, one on each axle. The first of these two papers was by Mr. W. Pestell, the electrical engineer

Digitized by Google

of the Lynn and Boston Railroad Company. The motors with which he experimented were, as a rule, of the G. E.-58 type. In each case the motors on the four-motor trucks were of exactly the same size as the two motors used for the same cars, so that there was a considerable excess of motor weight to be carried in the case of the four-motor equipments. To really make the experiments of value, the gross output of the motors should have been the same in each case—*i.e.*, the size of the motors in the four-motor equipment should have been half that of the two motors used in the other case. From actual trials and practice the author found that, as a rule, the four-motor cars consumed about 25 per cent. more energy than those equipped with only two motors. He obtained rather higher speeds, as is shown by the curves given in the report of the paper in the *Street Railway Journal*. We gather, however, that as the cars equipped with four motors were worked in the ordinary service, the increase of speed could not be great, as otherwise the cars would have got out of their schedule time, and would have had to wait behind at frequent intervals. The author's experiments on the heating of the motors was naturally greatly in favour of the four-motor equipments, his conclusion being that as regards the deterioration of the windings, the four-motor equipment had the advantage over the two-motor equipment in the ratio of 6 to 1. On the other hand, he thought that the extra wear, or, rather, the more wearing parts of the four-motor equipment, would be against them. Mr. C. B. Bigelow, the inspecting engineer of the Boston Elevated Railway Company, also read a paper on the same subject. In this case, again, we gather that the gross power of the four motors was considerably more than that of the two motors. In fact, the weight of the whole car with the equipment of four motors was 18 per cent. greater than in the other case. He found, however, as would be expected, that he would get much quicker acceleration with a four-motor equipment. In fact, a speed of 15 miles per hour was reached in only 68 per cent. of the time required by the two-motor cars, but 64 per cent. more current was used to give the same speed. In view, however, of the reduction of time, it only made an increase of about 12 per cent. of energy. From what we can gather from reading through these papers, and the discussions which follow the experiments made, were not really such as to bring out the relative advantages of the two methods. Although both the authors reported against the four-motor equipment, it does not follow that on lines such as the Metropolitan District Railway, where all the energy is used in accelerating the cars, that the gain from the four-motor equipment may not be very considerable. If, however, one tries to run cars equipped with four motors in the same schedule as those with two motors, no advantage would result.

Electricity in West Ham.—If not in its locality, West Ham at least compares most favourably with any of the other metropolitan boroughs in regard to its electrical undertaking. Already the Corporation electricity station has been found to be inadequate to the demand, and a scheme of large extensions and additions, both in connection with the lighting department and the projected electric tramways, is well advanced. Looking back on the past three years one is struck by the rapidity which has marked the progress of the electric light in the borough. Last year, for instance, the maximum demand at any hour was 578 kw., at the present time it is 1,000 kw., which shows a growth of close on 100 per cent. Consumers are now being connected at the rate of 12 per month, the charge per unit being 3·90d., which is the lowest of all the metropolitan boroughs having their own electric light undertaking, with the exception of Shoreditch. Among the various improvements introduced within the last year or so are the abolition of meter rents, the introduction of the system of allowing discounts, and the inauguration of the system of free wiring. The latest problem which is having the careful consideration of the Electricity Committee is as to supplying electric power for motive purposes during the daytime; and as the best means of demonstrating the many and various applications of electricity in this connection, the Corporation have organised an "electrical exhibition," which was opened to the public in the town hall on Monday last by the Mayor of West Ham. Having regard to the local nature of the exhibition, we were agreeably surprised to find so many well-known electrical firms represented; but this only goes to show the deep interest and sympathy with the Corporation in their latest effort to convince the ordinary householder of the great advantages which electricity has over all other motive powers. As showing the representative character of the exhibition, we may mention a few of the exhibitors. Thus Messrs. S. Z. de Ferranti show switchboard gear, rheostats, direct-current meters, etc.; while no less than seven different firms have electric motors, direct and alternating, driving various machines on view. These are Messrs. Geipel and Lange, the Langdon-Davies Electric Motor Company, the British Thomson-Houston Company, the General Electric Company, Messrs. Verity's, Messrs. Witting Bros., and the Vulcan Electric Company. The last-mentioned firm particularly demonstrates how suitably electric motors may be employed for various domestic purposes. We noticed, for example, electrically-driven sewing, mangling, washing, and knife-cleaning machines in operation, while an electrically-heated flat-iron also appeared to perform its work with due effect. Among the numerous other exhibitors we may mention Messrs. Jackson Bros., showing cooking apparatus, electric fans, telephones, etc.; the British Insulated Wire Company, cables; the Hart Accumulator Company, storage batteries; the Electric Lighting Boards Company, electric signboards for advertisement purposes, etc.; and the Renewable Lamp Company, showing glass-blowing for incandescent electric lamps. The stall of the General Electric Company is particularly attractive. Here may be seen the application of electricity for such things as kettles, cigar-lighters, and similar articles; while Messrs. Young and Marten have given special attention to electric cooking and heating apparatus of all kinds. An interesting feature of the opening day was the "setting" of an exhibition edition of one of the local papers on the spot by means of an electrically-driven Linotype machine. The town hall, which has been appropriated for the purpose, is artistically decorated with festoon cables and ornamental signboards, which lend a most brilliant effect to the surroundings. Mr. James K. Bock, the borough electrical engineer, whom we heartily congratulate on the organisation of the exhibition, is issuing a little pamphlet giving a brief *résumé* of the history of electricity, as well as a few of the methods by which electricity is produced and utilised for modern commercial purposes. In this we notice a good view of the engine-room at the West Ham electricity station, showing the 350-h.p. generators, before the addition of the two recent sets of 2,000 h.p. each. Altogether there is now some 6,000 h.p. of plant at the central station. Another view of a part of the transformer chamber at one of the electricity sub stations is equally interesting. It was the original intention of the committee to close the exhibition to-morrow (Saturday), but owing to the success which has so far attended the movement, it has been decided to extend the time for another week.

ILFORD ELECTRICITY WORKS.

Mr. Arthur H. Shaw, A.M.I.E.E., was born at Clapham, S.W., in 1867. He entered the employ of the Manchester Edison-Swan Company at Manchester as pupil, etc., in 1883, and in 1887 entered the works of Messrs. Fowler and Lancaster, in Birmingham, leaving them in 1889 to take the position of electrician to the Marquis of Salisbury at Hatfield. In order to gain further experience, especially in regard to electric traction, Mr. Shaw proceeded to the States in 1890, and entered the works of the Thomson-Houston Electric Company at Lynn, passing through

MR. A. SHAW, ELECTRICAL ENGINEER TO THE ILFORD URBAN DISTRICT COUNCIL.

the shops and "expert course" both in lighting and traction. In 1893 he went to Jamaica for the Thomson-Houston International Company to take charge in their interests of the Jamaica Electric Lighting and Power Company, Limited. Ten months later he was transferred as manager and engineer to the British Guiana Electric Light and Power Company, Limited. After 18 months in Demarara he returned to England in 1895, and joined the Otis Elevator Company as electrical engineer, but left them in 1896 to take the post of chief assistant to Mr. W. C. C. Hawtayne, consulting engineer. In 1898 he was appointed resident engineer to the Harrow Electric Light and Power Company, Limited, and was promoted to his present position in February, 1901.

that one-half of the streets now electrically lighted are not indicated on the Ordnance map, or at the most are shown by a few dotted lines indicating probable street extensions. In view of the rapid rate at which Ilford has grown and is growing, we hardly like to make any statement as to the population within the boundaries controlled by the Urban District Council. According, however, to the preliminary report of the census authorities, the population on March 31 was 41,229. The industries of Ilford are summed up in the statement that building residential houses finds employment for the bulk of the labour actually engaged in the district. The very large majority, however, of the inhabitants come up to town each day, an excellent service of trains being provided by the Great Eastern Railway.

It was in 1897 when the energetic councillors of Ilford first bethought themselves of electric lighting their district. Mr. W. C C. Hawtayne was called in to advise the Council, and his report was adopted in November of that year. A provisional order was applied for and obtained in 1898, and in October of that year Mr. Hawtayne received instructions to at once prepare plans and specifications for some 17 miles of electrical tramways. Powers for the construction of these have been obtained, and due provision was made for the same when drawing up the plans for the electric lighting station. There is a striking difference between the action of the Ilford Council in these matters and that of other town councils who have obtained provisional orders and held them for years without taking action. In Ilford, the decision of the Council to go in for lighting and traction has in each case preceded the granting of parliamentary powers. An advantage from the businesslike decision shown is that Mr. Hawtayne has been able to organise the work so that it can be carried out economically with the least inconvenience to the people. For example, when the lighting feeders and distributing mains from the power-house to the various parts of the district were being laid down, it was known exactly where the feeders for the tramway system would afterwards be required. Earthenware ducts were accordingly laid down, into which the tramway feeders will be drawn very shortly. By means of this there will be no need to break up the streets a second time,

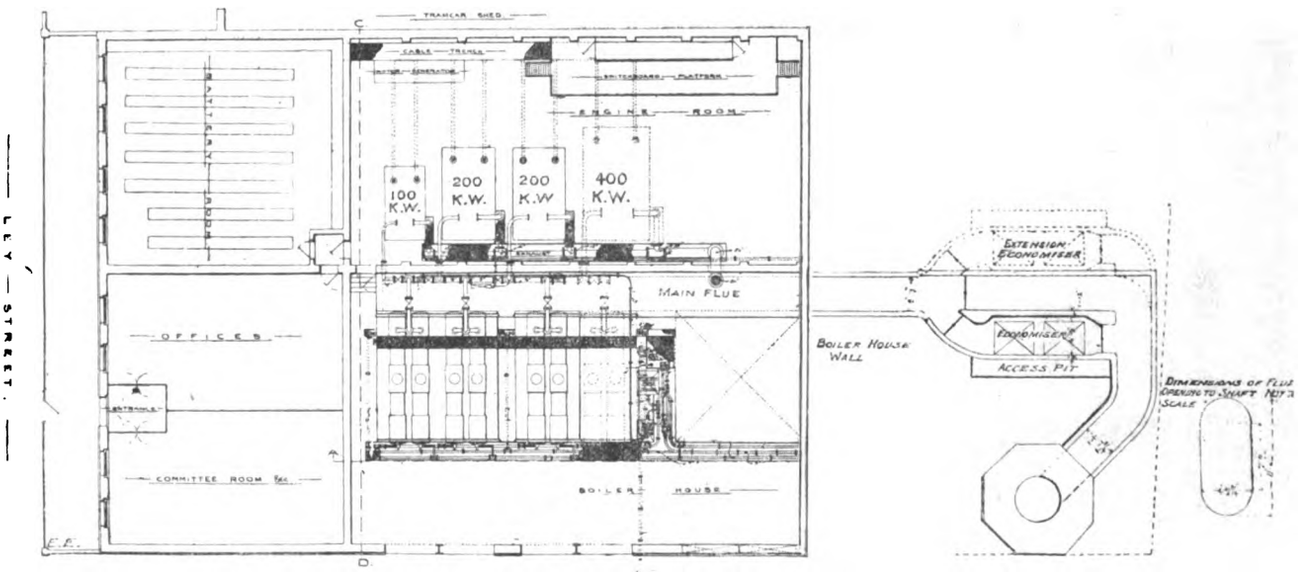

FIG. 2.—Plan of the Ilford Electricity Works.

Anyone who knew Ilford some 10 years ago would be utterly bewildered if he were to revisit it to-day. He would find green fields replaced by countless streets of houses, and also that most extensive building operations were being carried on in all directions. As an example of the progress made, one has only to compare the map which we give herewith of the streets which are now electrically lighted with the latest Ordnance map. The date of this Ordnance map is only 1897, and yet we should say roughly

as has had to be done at nearly every town we know of when making provision for electric traction.

In 1897 a site for the works was secured in Ley-street, which is, as shown on the map (Fig. 1), in a central position. The area of the site obtained is quite sufficient to meet the needs of the district as far as power works are concerned, and there is also room on it for the construction of carsheds in connection with the electric tramways. The designs for the buildings were got out by Mr. H. Shaw, the surveyor

Digitized by Google

to the Ilford District Council, who also superintended the erection of these buildings. A general arrangement drawing (Fig. 2) shows the positions of the various parts of these works, while Fig. 2 is a cross-section through the same. In the plan the chimney shaft is shown, owing to the exigencies of our space, somewhat nearer to the boiler-house than is actually the case. The arrangement of the economisers

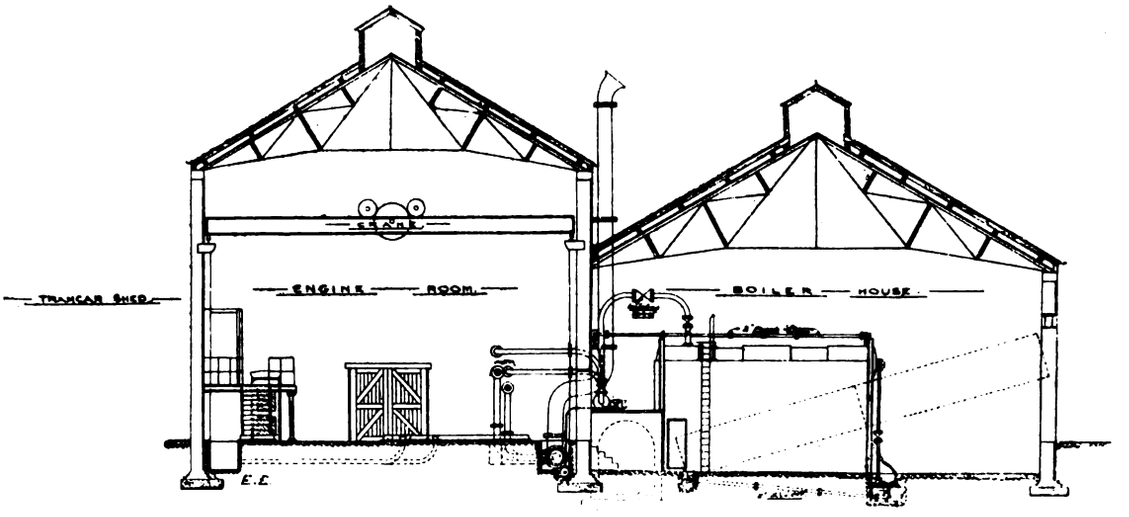

FIG. 3.—Section of the Ilford Electricity Works.

is also shown in the plan. It will be seen that when the extensions are completed there will be two of these useful adjuncts, and they will be so arranged that either half can be shut down for cleaning. Again, if need be, they can both be closed down, and the whole of the gases passed into the chimney by means of the by-pass between the two economisers. As will be seen from the photographs, the interior of the boiler-house and engine-house is lined

arranged in two batteries of two and one boiler respectively. Each boiler is composed of 12 sections, each section comprising nine tubes in height, the tubes being 4in. in diameter and 16ft. long, expanded at the ends into staggered headers. The headers are provided with handholes placed opposite the end of each tube to permit cleaning and removal and renewal of a tube, the handholes being provided with caps fastened with bolt, clamp, and cap nut. The several sections are connected at each end to two steam and water drums 36in. in diameter and 24ft. 4in. long, and at one end with a mud-drum for collecting the deposit. The boilers are constructed for a daily working pressure of 200lb. per square inch. Each boiler is fitted with steam superheater. There is also a Green's economiser of 196 pipes in the main flue, fitted with

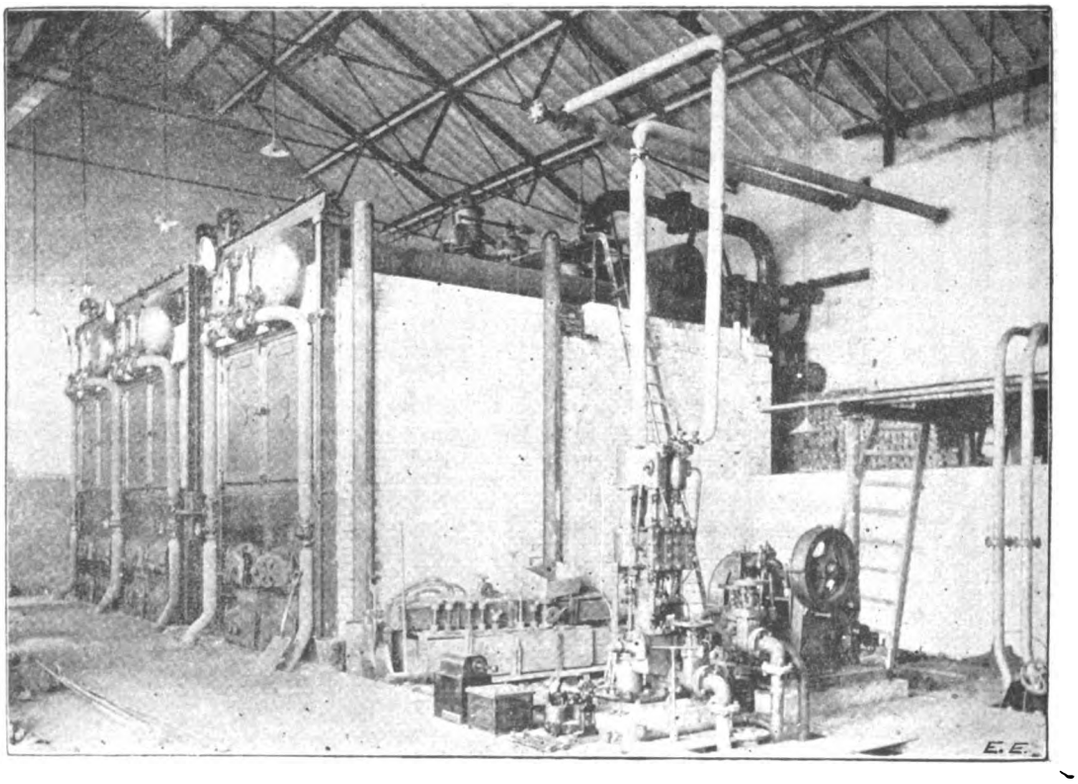

FIG. 4.—View of the Ilford Boiler-House.

with glazed bricks. The walls of the buildings are also of bricks, as is the chimney shaft, which is 185ft. high. The internal diameter of this shaft at the top is 8ft. Before leaving the buildings to pass on to the engineering plant, we must congratulate their designer on their businesslike appearance, and on the ample space which he has allowed in each department.

The boilers are of the Babcock-Wilcox type, three being at present installed, each with a heating surface of 2,197ft.

scrapers, etc. A gallery and ladder are fitted across the tops of the boilers for facilitating access to the fittings. Beyond the three boilers now fixed, which can be seen in Fig. 4, there is a space for one more boiler of the same size before coming to the feed pumps and gear connected therewith. There are two of these pumps, the first being of the compound duplex steam type. The other is of the treble barrel plunger type, 3½in. by 6in., driven by an electric motor made by J. H. Holmes and Co. Messrs.

Digitized by Google

Babcock and Wilcox have also supplied and erected all the mild-steel steam-piping, fitted with wrought flanges, together with the necessary valves, which are so arranged that the breakdown of any portion of the steam-main will not interfere with the working of more than one engine or boiler at any time. The pipes are supported by hangers, and provision is made for expansion and contraction, the pipes being lagged with non-conducting composition. A steam-trap is also provided. The complete system of cast-

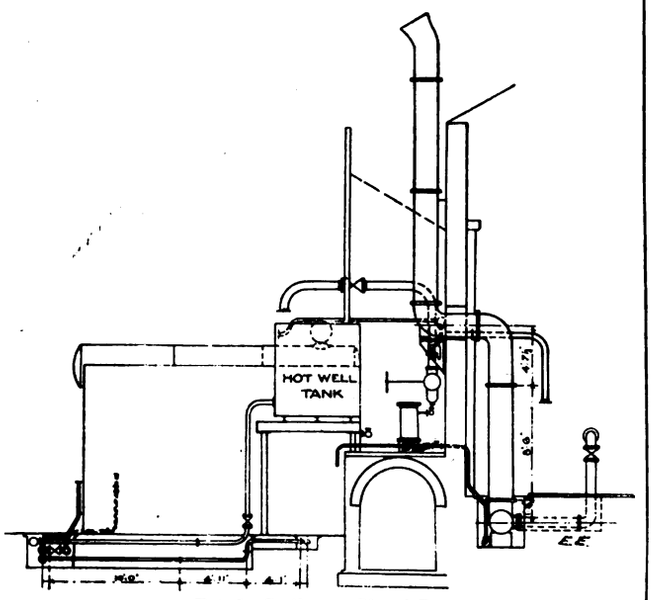

FIG. 5.—Section on Line A B.

iron exhaust pipes and valves fitted to each engine has also been erected by the firm, as well as the wrought-iron feed pipes, which are arranged in duplicate, so that either pump can feed into either main. In addition there is a separate injector to each boiler, arranged so that any injector can feed any boiler. A storage tank, capable of holding 2,000 gallons of water, erected on girders is provided in order that the water flows naturally to the pumps and injectors. A complete system of drain pipes has been erected. The general arrangements of these pipes are shown in Figs. 5, 6, and 7.

The generating plant in the engine-room consists of three engines at present, while a fourth engine is now on order and will soon be delivered. Each of these consists of a General Electric direct-current dynamo, coupled to an engine made by Willans and Robinson, of Rugby. The engines manufactured by this firm are so well known

they are designed to give 220 kw. without overheating. With ordinary conditions for lighting they run as shunt-wound dynamos, whereas when supplying the traction load they have a series coil assisting in the excitation, so that they are somewhat over-compounded. For instance, when working on the traction load, the voltage on open circuit would be 500 and at full load 550. Through the courtesy of Messrs. Willans and Robinson, we are able to reproduce in Figs. 11 and 12 the results obtained with the 200-kw. machines on trial. It will be seen that at 460 volts the steam required per kilowatt-hour was slightly below 34lb. The smaller set gave even better results, the consumption being as low as 32·39lb. per kilowatt-hour. These engines are at the present time working non-condensing, but if the supply of water from the artesian well now being sunk is found to be ample, it is likely that condensing gear will be added at an early date.

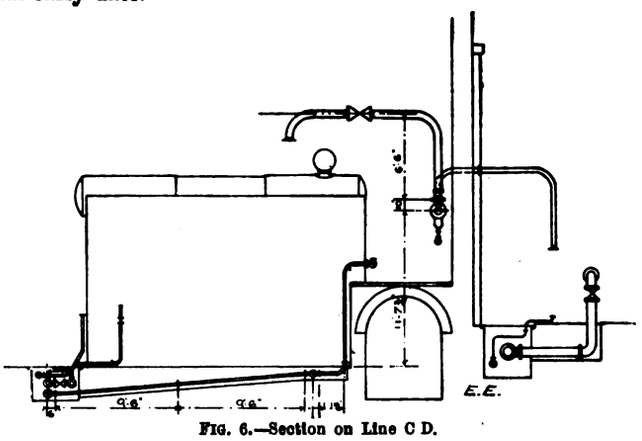

FIG. 6.—Section on Line C D.

Before proceeding to describe the switchboard, a few words as to the balancing boosting set may be of some interest. This consists of four independent dynamos coupled together with their axes in line. The two inner machines are balancers, and each armature has a capacity of 95 amperes, 220 to 250 volts. The two outer machines are boosters, and have each an output of 120 volts, 175 amperes. The combination runs at a speed of 850 revolutions per minute. The machines are of the firm's light four-pole type, and of their usual design, with circular pole-pieces and cast-steel magnet system. The windings are embedded in slots on the armature.

The main switchboard is arranged for three-wire lighting, and has been supplied and equipped by Messrs. Kelvin and James White, Limited, of Glasgow and London. The diagram of connection used on this board is shown in Fig. 13. The switchboard is mounted upon a platform near

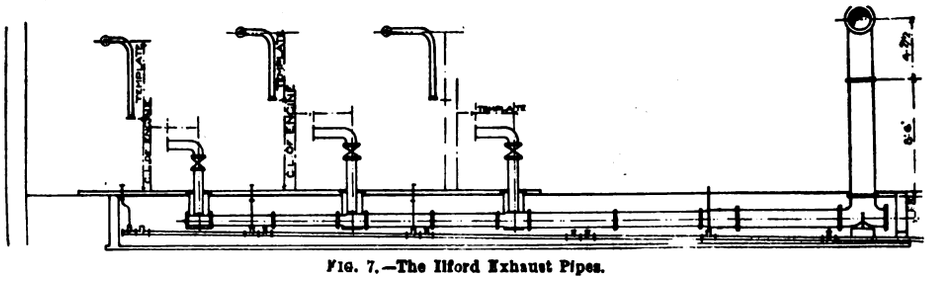

FIG. 7.—The Ilford Exhaust Pipes.

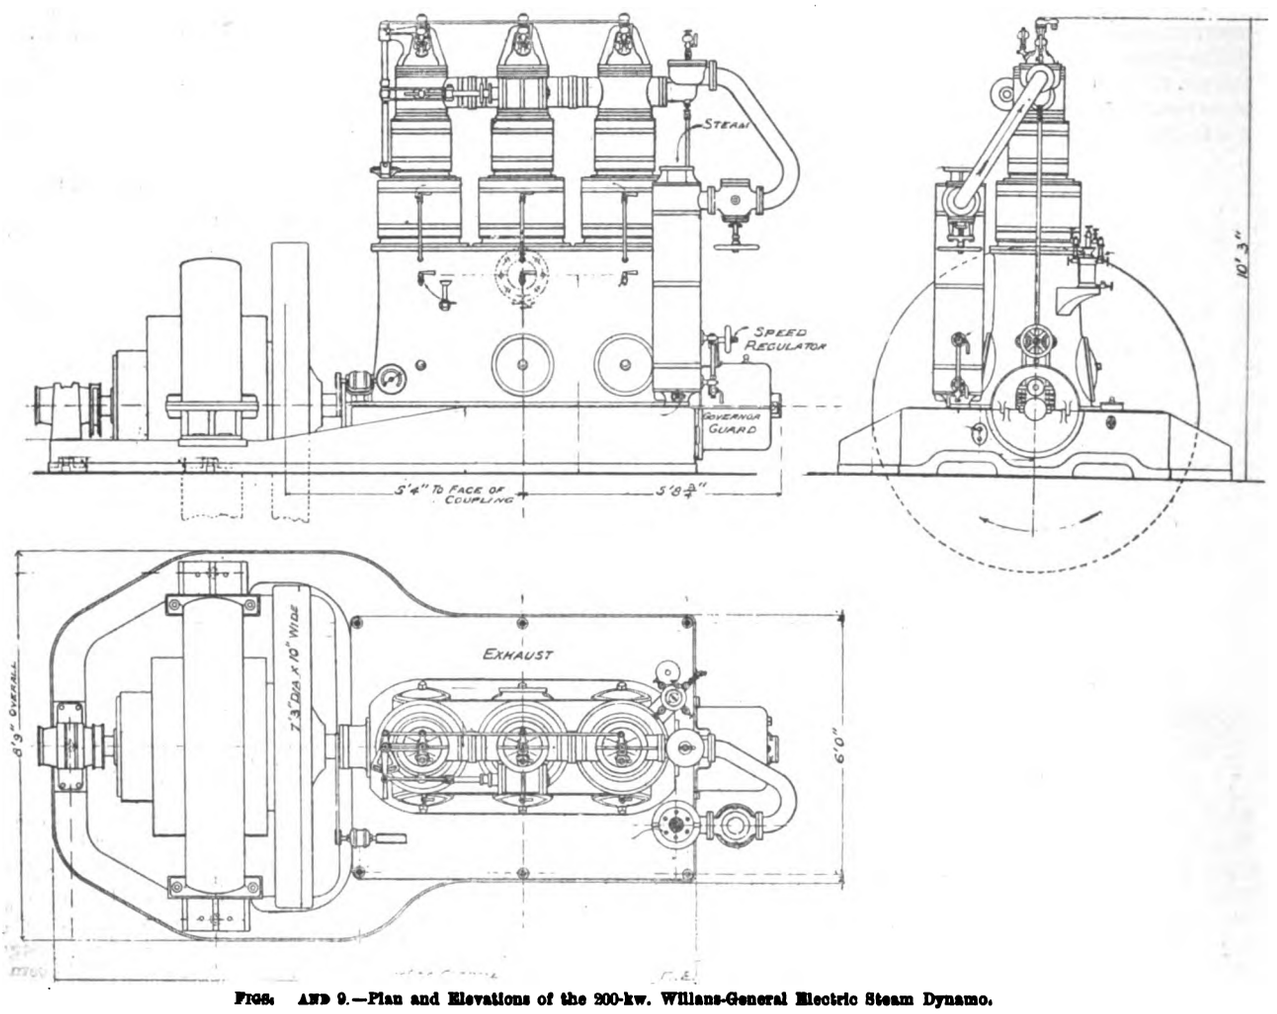
that no special description is required of the same. We give, however, in Figs. 8 and 9 a plan and elevation of one of the 200-kw. sets, of which two have now been provided. It will be seen from this drawing that two of the engines are of the three-crank type, and that there is provision on them so that the governors are able to alter the cut-off quickly in case the load is varied between wide limits in a short space of time, as is frequently the case in traction working. The smaller engine, which is seen to the left of the engine-room in the photograph from which Fig. 10 is prepared, is a 100-kw. These dynamos of the General Electric Company's make are practically similar to those supplied by the same firm for the Wigan electricity works, which were described by us in full in our issue of Feb. 1. While the normal output of the larger machines is of 200 kw.,

what will be the centre of the engine-room when the works are completed—*i.e.*, when the wall, which is shown in Fig. 2, is extended out to the line at which the flues curve out into the economisers. The switchboard (Fig. 14) consists of polished marble slabs mounted on a steel framework, with an ornamental metal top, having an electrically-driven clock of this firm's make fitted at the centre. The total length of the switchboard is 19ft. 6in., and it is divided into 10 separate panels. The four panels at the left contain all the instruments and switch gear for the negative side of the dynamos and feeders. The four panels at the right contain all the instruments and switch gear for the positive side of the dynamos and feeders, and the two panels at the centre contain all the instruments and switch gear for the batteries, boosters, balancers, and middle wire. The switchboard as at present

Digitized by Google

arranged is capable of dealing with three dynamos and 11 three-wire feeders, as well as two boosters, two balancers, two batteries, etc. Space, however, is provided by which instruments and switch gear for three other dynamos and one feeder can be added at a later date. All the instruments mounted on the board are of the Kelvin type, and include ampere gauges of the sector and edge-wise pattern, "S.R." (siphon recorder) voltmeters, recording voltmeters, and earth-current recording ammeter. The top panel on the positive and negative side contains all the switch gear and instruments for the feeders, as well as the plugging bars for the dynamos, boosters, and feeders. The two lower panels on the positive and negative side contain all the instruments and switch gear for the three dynamos,



FIGS. AND 9.—Plan and Elevations of the 200-kw. Willans-General Electric Steam Dynamo.

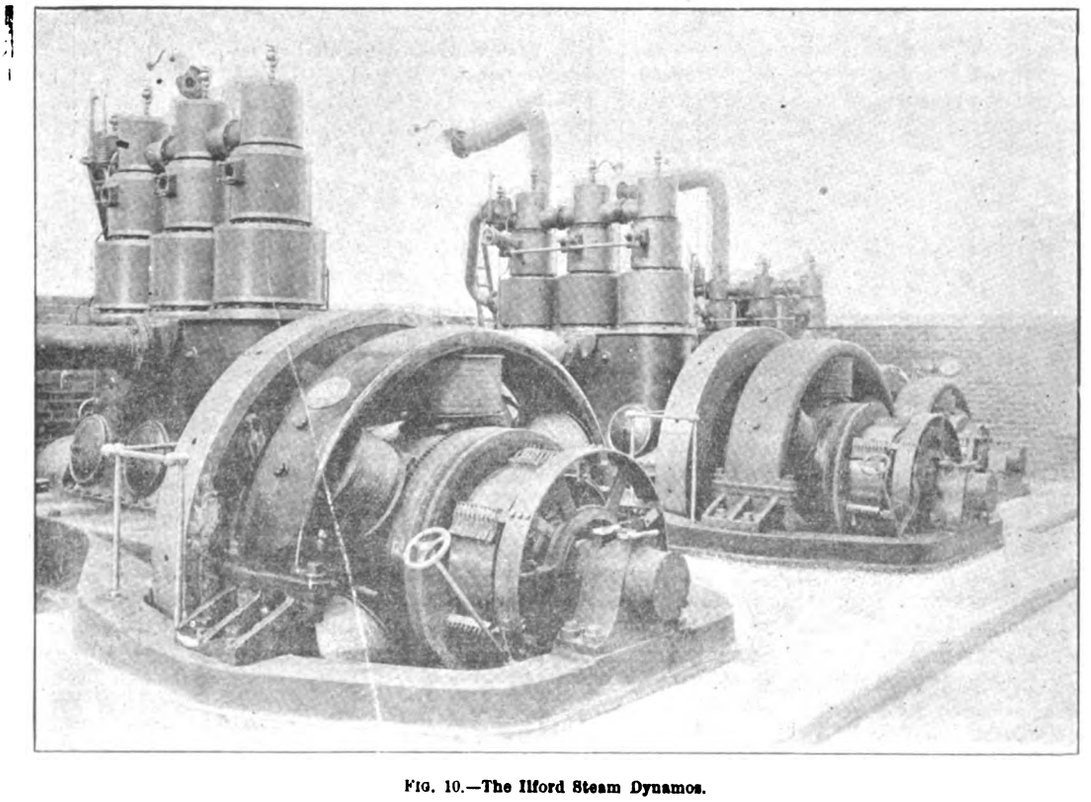


FIG. 10.—The Ilford Steam Dynamos.

the two other panels at the bottom being left spare for the addition of switch gear and instruments necessary for three extra dynamos to be added at a later date. The two large dynamos are provided with double-pole throw-over switches

in order that they can be thrown over either to traction or lighting. These throw-over switches are neatly arranged with a catch, so that when the circuit is being broken from the one set of contacts the catch prevents an accidental throw-over into the lower set of traction contacts unless such a connection is required. The automatic cut-outs fitted in the dynamo and feeder circuits are of Ferguson and White's patent type, and are arranged to work either as a maximum-current cut-out or a reverse-current cut-out. During working it is set as the former, and when it is desired to shut down a machine it is changed to act as a minimum cut-out. This change is made simply by turning over a small key

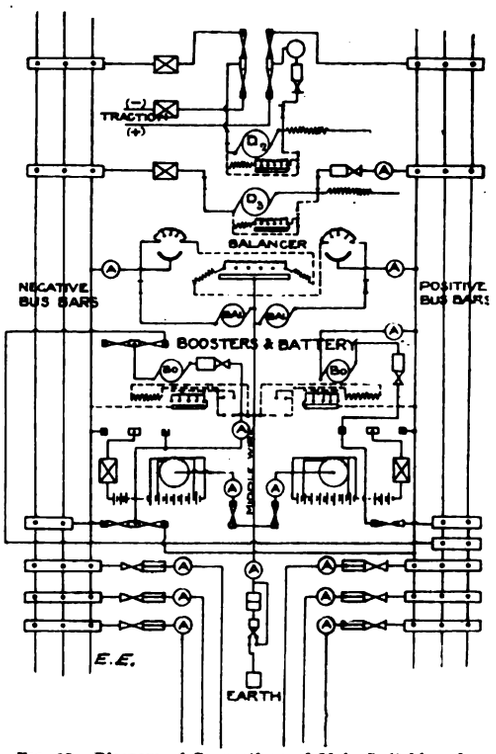

FIG. 13.—Diagram of Connections of Main Switchboard.

from the position marked "maximum" to that marked "minimum." By the adoption of this type of cut-out it is impossible to hold the switch closed should an excessive current be passing, and the same handle is arranged so that it can be used as an ordinary switch. Carbon breaks and asbestos screens are provided for taking and effectively wiping out any spark that may occur. The fuses on the dynamo and feeder circuits are of the plug type, and are thoroughly protected by means of porcelain covers. On the centre panel and at the top are mounted the ampere gauges for

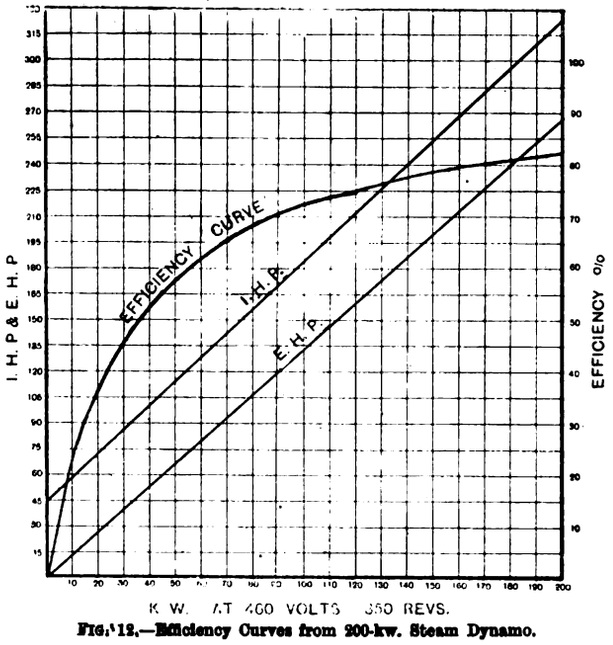

FIG. 12.—Efficiency Curves from 200-kw. Steam Dynamo.

the balancers, batteries, and middle wire, as well as the two recording voltmeters. Immediately below the ampere gauges are fitted the voltmeters for the batteries and bus

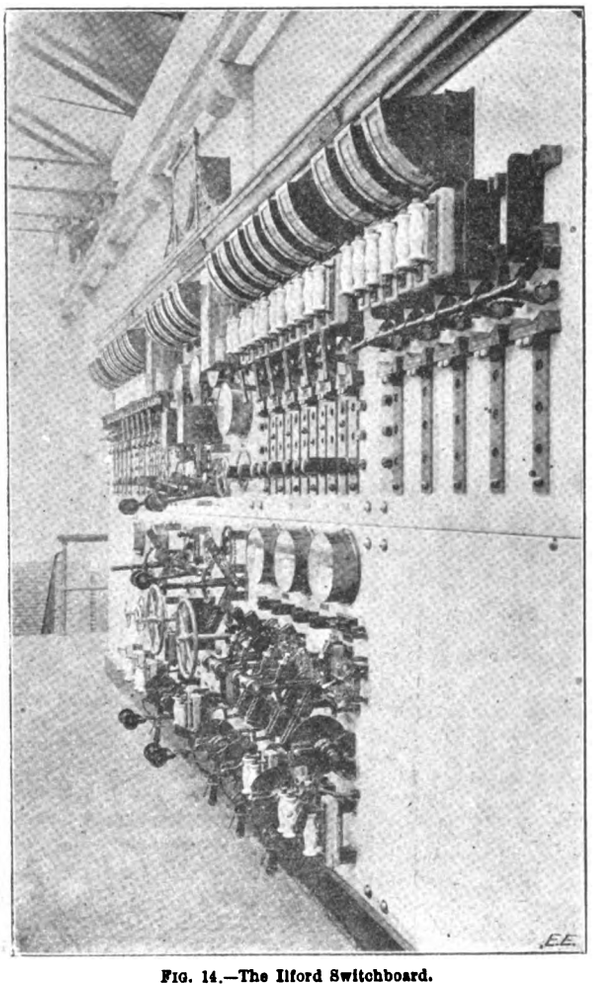

FIG. 14.—The Ilford Switchboard.

bars, as well as the two Kelvin electrostatic multicellular voltmeters for the feeders. On this panel also are mounted the booster ampere gauges, as well as the single-pole emergency switch for the batteries. On the lower centre panel is mounted the switch gear for the balancers and boosters, as well as the handwheels for the battery-regu-

Digitized by Google

lating switches. The battery-regulating switches themselves, however, are mounted on a separate marble slab (Fig. 15) which is let into the battery-room wall, the connections to the cells being run directly from the back of this board. The switches themselves are actuated from the main board by means of shafting geared to the handwheels

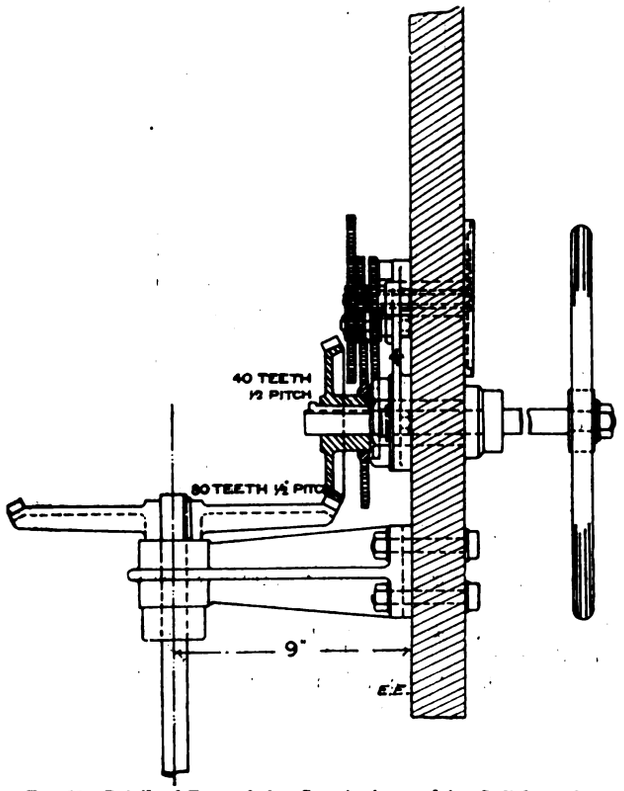

FIG. 15.—Details of Transmission Gear to Accumulator Switches. One revolution of the hand wheel shifts the contacts one cell.

(Fig. 15), and as arranged at this station has a very neat and compact appearance.

In order that the attendant working the switchboard may know when working these handwheels that he is not leaving the accumulator switch in the wrong position, a system of electric bells has been provided, which will ring when the switch is in an intermediate position between the two contacts. Another interesting feature is the use of arrows on the handwheel in order to indicate approximately the right position in which the wheel should be left. The space between the two points of these arrows is practically equal to the distance through which the wheel has to be used to overcome back-lash when reversing the direction of the rotation. Arrangements are also provided on the lower centre panel by which the boosters, ordinarily used for charging the batteries, can be connected to vertical bars on the positive and negative side and can thus be used to raise the voltage of any set of feeders. The Kelvin earth-current recorder and short-circuiting switch, for use with the earth circuit, are also mounted on the centre panel. On the wall below the platform are fitted the two Aron battery meters, as well as the three Thomson dynamo watt-hour

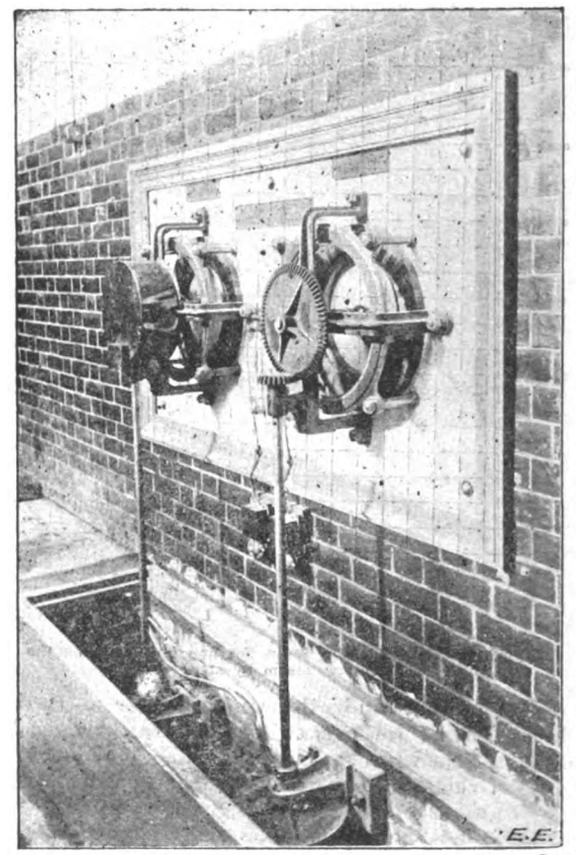

FIG. 16.—View of the Accumulator Regulators and Transmission Gear for working the same from the Switchboard.

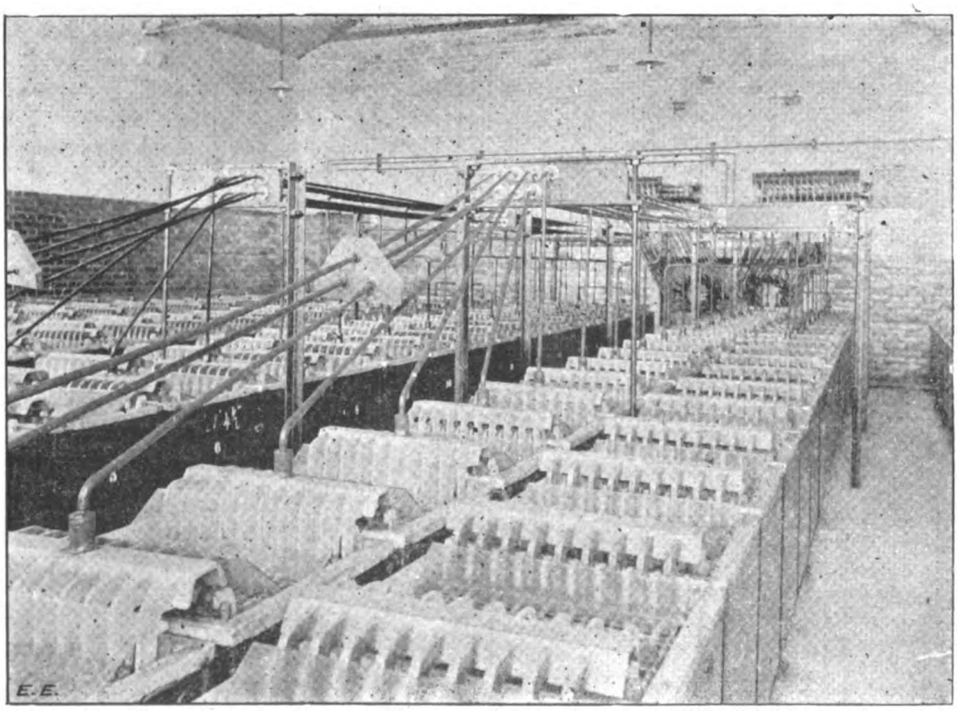

FIG. 17.—View of the Accumulator Connections.

Digitized by Google

meters. The whole of the work on this switchboard has been carried out by Messrs. Kelvin and James White, Limited, and the same firm have also been responsible for the connecting up of the machines and accumulators

amperes for three hours, at 460 volts. The containing boxes are of wood, lead lined, each cell consisting of 19 plates supported on glass slabs and separated by glass tubes. The cells are erected on single-tier stands,

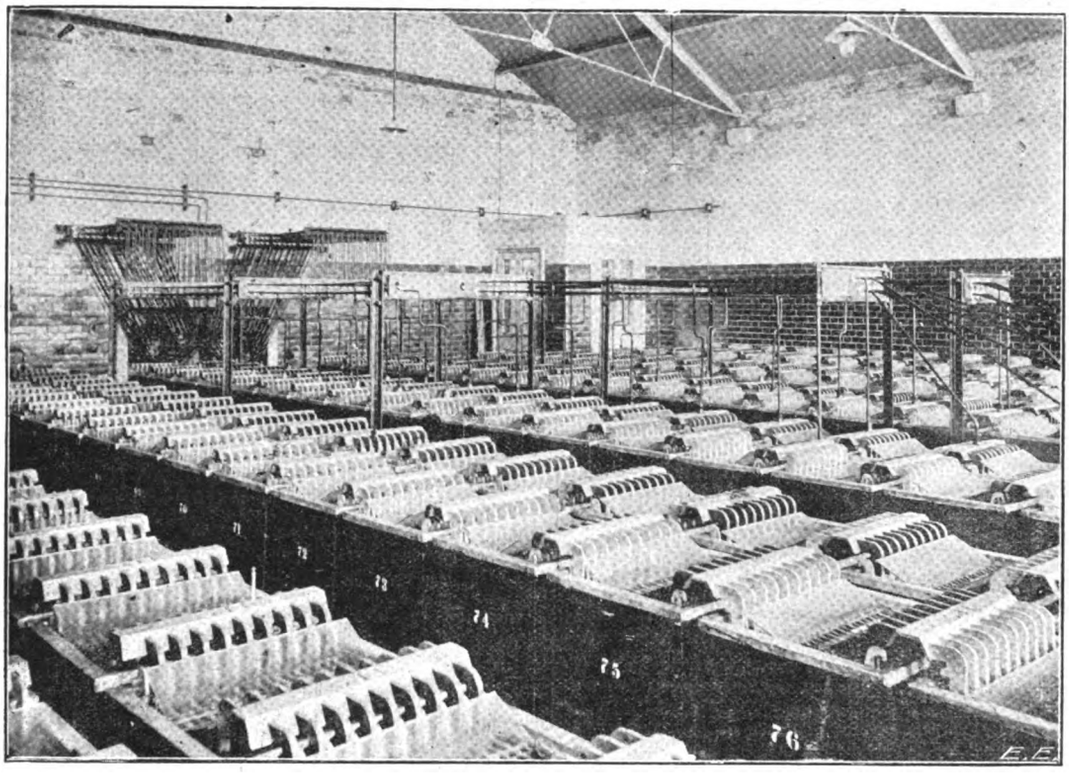

FIG. 18.—General View of the Ilford Accumulator-Room, with E.P.S. Accumulators.

to their respective switches. The connections in the accumulator-room are carried out by means of copper rods, which are painted to protect them from acid fumes. In Fig. 17 we give a view of these connections, which have been equipped in a most workmanlike way.

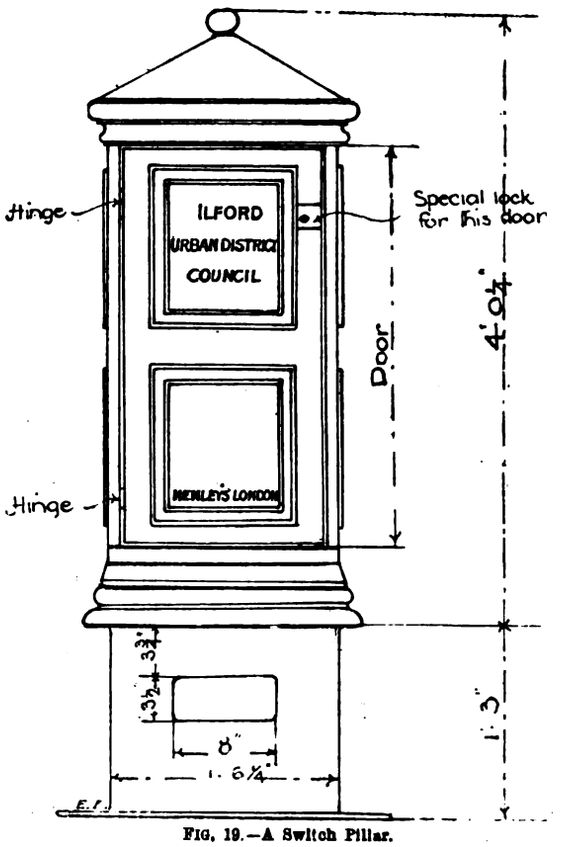

FIG. 19.—A Switch Pillar.

The accumulators (Fig. 18) were supplied by the Electrical Power Storage Company, and are of the K.L.P. type. There are 270 of these cells provided, each of which is capable of discharging at 400 amperes for one hour, or 200

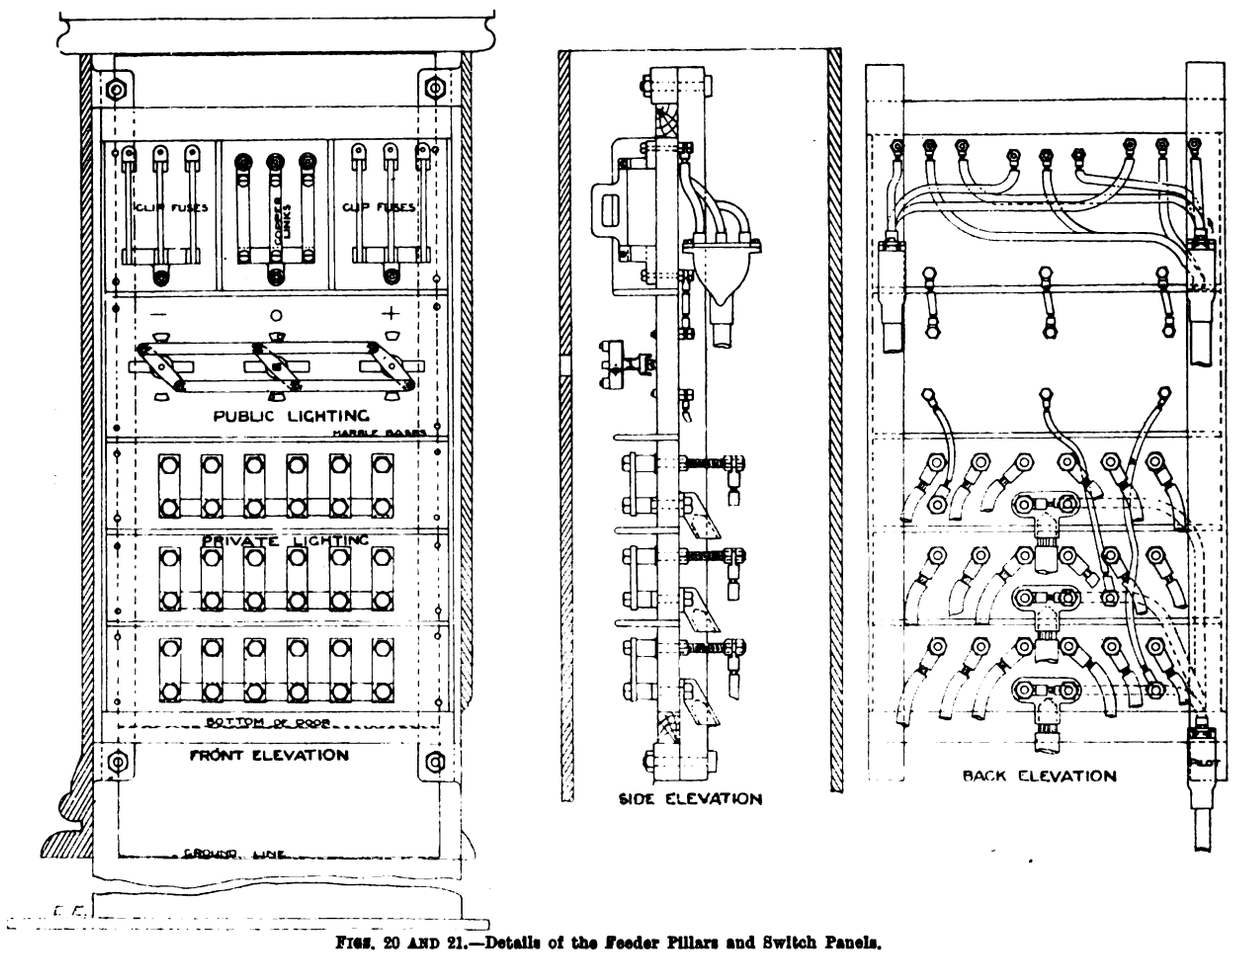
and the weight of each cell complete with acid is approximately 170lb. As will be gathered from the illustration (Fig. 18), the accumulator-room is a spacious one; in fact, we know of no accumulator-room in the kingdom the arrangement of which we prefer to those we have seen at Ilford. The only objection in the same is that the regulating cells are not connected on the earth side of the batteries, so that there is practically 500 volts between the cells on the opposite sides of the centre of the alley.

The supply of electricity throughout Ilford has to be given over an area approximately three miles long and two miles broad. This is done on the low-tension three-wire system at 460 volts between the outers. Nine feeders in all are included in the first scheme, and these consist of either triple-concentric or concentric mains, which are armoured and laid direct in the ground. The three-core pilot cables laid to the end of each feeder are also armoured. The distributing mains, on the other hand, consist of three single cables, which are only lead-covered, and are laid in wooden troughs on the solid filling-in system. The sections of these are respectively ·12, ·06, and ·12 square inch. In the usual way this distributing system would be connected throughout, but disconnecting boxes are placed at the end of each street, by means of which the mains can be divided up when required. Instead of using street feeder boxes, the whole of the feeders are led to feeder pillars, which are much more accessible than street boxes. One of these feeder pillars is shown in Fig. 19, while Figs. 20 and 21 show the apparatus contained in this pillar. The street-lighting—of which a large amount is being done, there being at the present time 306 incandescent lamps and 33 arc lamps in use—is all carried out by means of independent cables from the feeder pillars. The arc lamps are run five in series off one side of the three-wire system. The whole of the cables, amounting to more than 60 miles in length, were manufactured and laid by the W. T. Henley's Telegraph Works Company, Limited. The same firm have also laid about seven miles of stoneware ducts and drawing-in boxes, which are to be used for extensions and for the tramway feeders.

The street-lighting has been let in two contracts. The first of these was for the arc lighting in the main road, and was awarded to Messrs. Verity's, Limited. This firm have

Digitized by Google

supplied the 33 double-carbon arc lamps of 10-ampere capacity, referred to above. Each lamp is adjusted to burn in series with four others across the 230-volt mains, and is under a guarantee to keep within 3 per cent. of 45 volts at its terminals. They are erected under a specially-designed hood and carrier on the tops of the traction poles (Fig. 22), each of which is also provided with two ornamental bracket-arms carrying incandescent lamps. The poles themselves are of steel, the bases being of massive design in cast iron. The switch gear, automatic cut-out, resistances, etc. (Figs. 23 and 24), are all carried in the bases of the poles, and are of a specially compact and suitable design. In addition to the above arc lamps and posts, there are a further 40 traction pillars only already erected and used to carry incandescent lamps. Provision is made on these for the addition of arc lamps themselves, with heads corresponding to the others when required. The whole of this contract was placed with Verity's, Limited, the carrying out of which has been supervised by Mr. C. S. Northcote, M.I.E.E., their newly-appointed manager.



FIGS. 20 AND 21.—Details of the Feeder Pillars and Switch Panels.

The incandescent street-lighting has been done by the Improved Electric Glow Lamp Company, who have supplied the new posts required to support the lamps. This was necessitated because the gas company refused to sell the gaslight standards. In certain of the newer districts, however, these standards are already the property of the Council, so that only new lanterns will be required. In fact, the opposition of the gas company has gone so far that they not only refuse to sell or to remove their lamp-posts, but have also continued to light the same free of cost. In certain instances they have even gone so far as to instal two of the latest type of incandescent gas burners in order to show what they can do in the matter of street-lighting. In view of the fact that there is often barely more than a foot between the two lanterns, the absurdity of the present condition of street-lighting in Ilford will be appreciated. To revert to the electric lamp-pillars supplied by the Improved Glow Lamp Company, they are fitted with copper lanterns glazed on four sides, each fitted with two, three, or four-light fittings and improved reflector incandescent lamps. These lamps consume 60 watts per lamp, and are stated by the company to give 80 c.p. per lamp in the desired direction. The fittings consist of a special compact double, triple, or quadruple lampholder, in which the lamps are placed at an angle of 20deg from the horizontal, double lampholders being fitted in lanterns placed on either side of the street the same distance apart as the old gas lanterns, triple lampholders (two lamps in line and one at right angles) at the corners of branch streets, and quadruple lampholders at cross streets. The light given out by the filaments of each lamp is collected by the silvered top surface of these now well-known lamps and distributed over a given area below the horizontal in such a manner that the light from each individual lamp crosses that from the next in line with it about 8ft. above the ground, thus producing an even lighting area of high candle-power, covering the whole of the space, road, and pavement between neighbouring lamp-posts. From recent tests the company claim that two 60-watt Improved Electric Glow lamps placed 100ft. apart will illuminate an area of 1,000 square feet with a mean candle-power of 60. Each lamp-post is provided with a D.P. damper pattern cut-out specially mounted and covered in, and fixed in the base of the post. All the posts are wired in groups and controlled from section pillars in the usual manner, alternate lamps being on different circuits.

The scale of charges for private lighting at Ilford can, at the option of the consumers, be either a flat rate of 5d. per unit or a sliding scale rate on the Wright maximum-demand system. If this latter scale is selected, the consumer will pay 8d. per unit for the first hour's average consumption per day of his maximum demand, and 2d. for all above this. In order to encourage the supply of electricity to consumers, the Ilford Urban District Council have arranged to wire consumers' houses on the deferred payment system The one advantage of this which it appears to us is likely to be most appreciated in Ilford is that any consumer can get his house wired by the contractor who has all the free wiring work to do, and can then pay cash down for the same. Such a large number of the inhabitants own their own houses that they are quite prepared to expend the necessary money in the first instance, but they will gain a great advantage from the low rate at which the Council

Digitized by Google

will do the work, and from the fact that the same is done under the supervision of the Council's engineers. The station has been giving a supply for certain hours in the day for some weeks, but the formal opening of the station is to take place on Saturday next. The Council then propose to throw the station open for the ratepayers to inspect. There is also under consideration a proposal that the station shall be open for an hour on a certain day of each week, in order that the inhabitants of Ilford may go

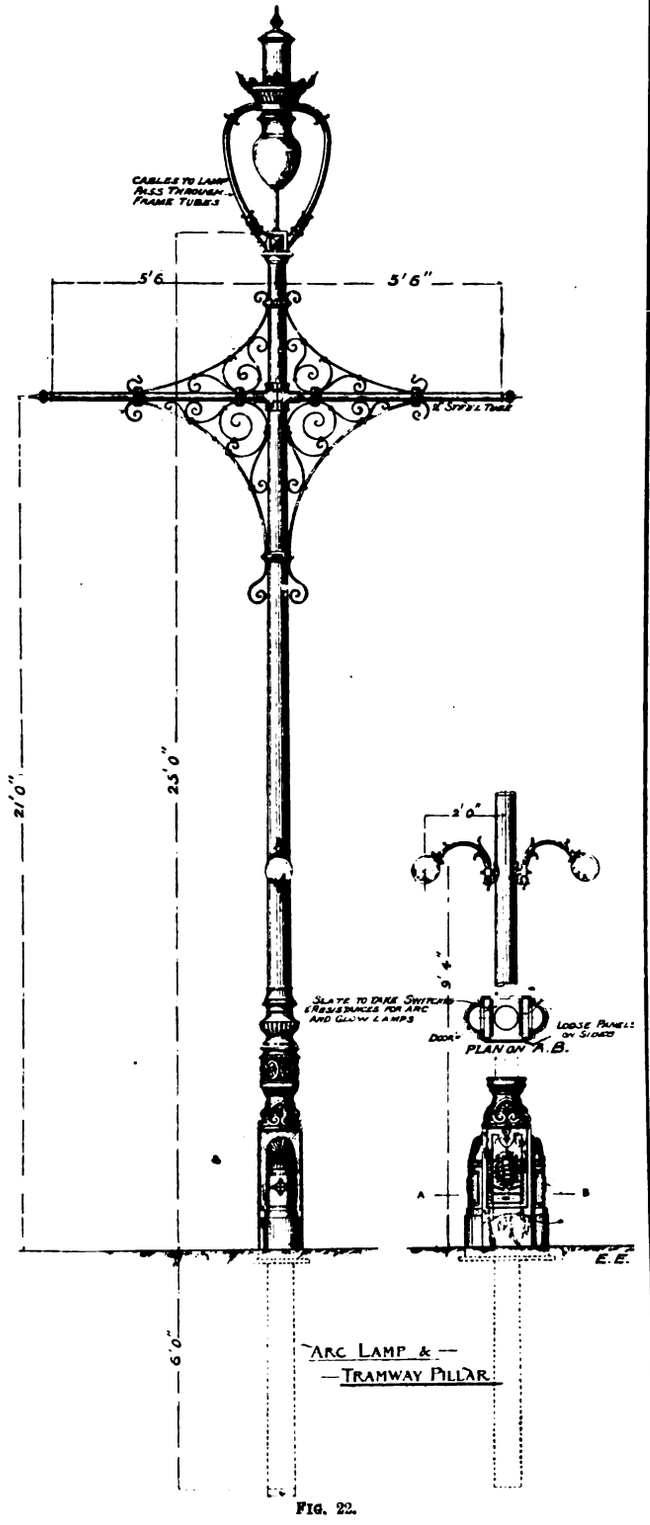


FIG. 22.

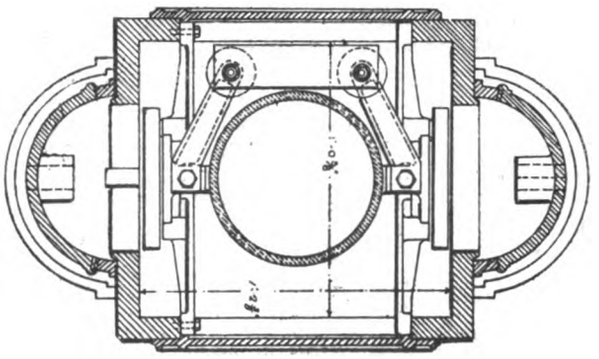
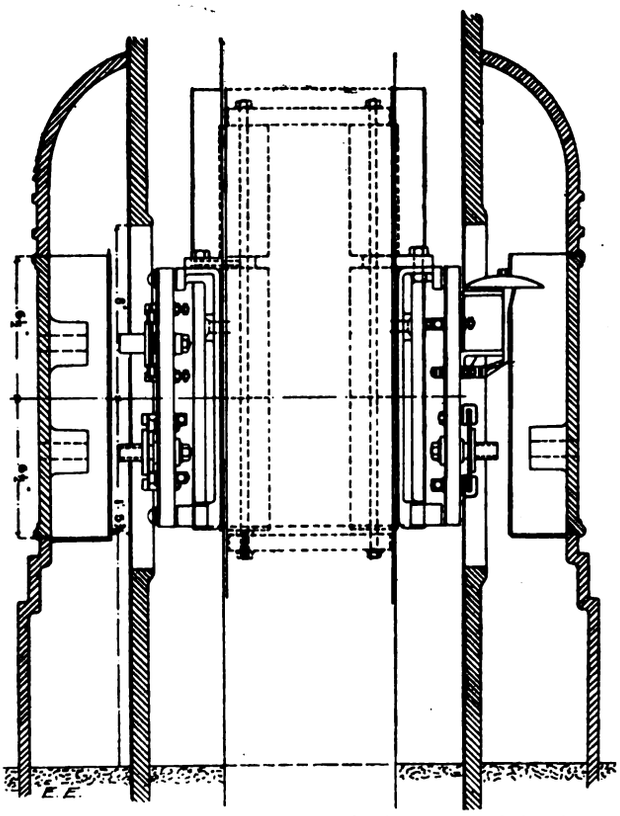
and admire the good works which they have secured under the able advice of Mr. W. C. C. Hawtayne and their surveyor, Mr. H. Shaw. Mr. A. Shaw, the borough electrical engineer, has been responsible for the carrying out of the work, and is to be congratulated on the prompt way in which he is having the various plant completely equipped for work.

Mr. Hawtayne is now urging forward the electric tramway work, and several of the specifications are ready for issue. These electric tramways when completed will form a through connection to Barking, and thence to West Ham, also through Ilford to East Ham and to Barkingside, and in the East along the High-road to Romford-road to





FIGS. 23 AND 24.—Base of Traction Pole, showing Arc Lamp Switch Gear.

Chadwell Heath. The track along the Romford-road and the High-street will be double throughout, with trolley wires supported from centre poles. In the other streets

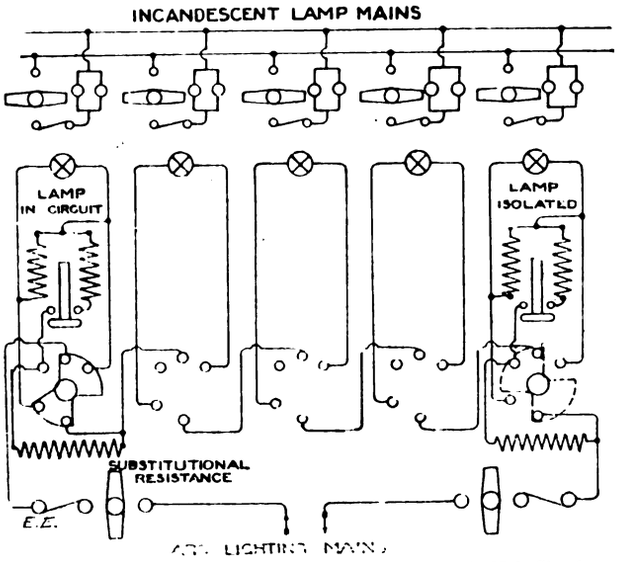


FIG 25.—Connections to Arc and Incandescent Lamps in Main Streets.

the line will chiefly be single track with side-pole supports, with turnouts or short lengths of double track as indicated above. The tramway leading to Barkingside passes along

Digitized by Google

Ley-street, past the generating station. Two overhead trolley wires will be provided throughout to do away with the necessity of employing frogs for turnouts, and the line will be constructed in sections not exceeding ½ mile in length. Guard wires and all usual accessories will be provided. The rails will be of the girder pattern, 100lb. in weight, electrically bonded and supported on 6in. of concrete, with stone setts between rails and tracks and 18in. outside of tracks. The overhead trolley wires will be supplied at 500 volts from the generating station through feeders laid partly solid and partly drawn into conduits. The usual feeder pillars will be provided, together with telephone equipments and switching gear for isolating the half-mile sections. There will be 12 double-deck motorcars, to seat about 43 passengers, each provided with two 25-h.p. motors, and all usual controlling gear, emergency switches, etc. The cars will be lighted electrically. The car-sheds will be erected on land adjoining the power station and additional generating plant will be provided at the works, also designed, as is the present plant, to be suitable for either traction or lighting purposes as required. A number of steel poles along the High-street and Romford-road have already been erected, and these poles will serve both the purpose for supporting the trolley wires and for public street-lighting by means of arc and incandescent lamps. Intermediate poles will very shortly be erected when the permanent way is started. The total length of the tramway route now being equipped is 6m. 3f. 3·25ch., made up of 2m. 3f. 6·8ch. of single track and 3m. 7f. 6·45ch. of double track.

OBITUARY.

Sir Courtenay Boyle.

The sudden death of Sir Courtenay Boyle, permanent secretary to the Board of Trade, through heart failure, will be sincerely regretted by electricians who recognise his remarkable ability for the position he so ably filled. Born in Jamaica in 1845, the eldest son of Cavendish Spencer Boyle, grandson of the seventh Earl of Cork, Sir Courtenay Boyle was educated at Charterhouse, and subsequently at Christ Church, Oxford. From 1868-73 he was private secretary to the Viceroy of Ireland, and again from 1882 85; from 1873-85 he also occupied the position of Local Government Board inspector; from 1886-93, assistant secretary to the Board of Trade; and in 1893 he attained the office of permanent secretary to the Board of Trade. Created a C.B. in 1885, he was made Knight Commander of the Bath in 1892. On railway matters he was, of course, a recognised authority, while one of his favourite themes on which he was never weary of dilating was the need of better commercial training for the youth of England if the nation was to keep its place in the struggle for existence. Sir Courtenay, in his position as permanent secretary to the Board of Trade, has been identified and chiefly responsible for much of the important work which has been accomplished by the department in recent times. Probably his greatest and most arduous task was that which he performed as joint commissioner with Lord Balfour in revising the rates, tolls, and charges of the railway companies in the United Kingdom. A mere recapitulation of the Acts the adoption of which Sir Courtenay Boyle recommended to Parliament would occupy more space than we have at our disposal. We may mention, however, that in 1888 he had much to do with the Railway and Canal Traffic Act, and a year later with the Regulation of the Traffic Act. The latter was a very important statute, empowering the Board of Trade to call upon railway companies to fit their passenger trains with continuous brakes, as well as to interlock their points and signals. The year 1894 witnessed the passing of another Railway and Canal Act, designed to check the raising of the rates which Lord Balfour and Sir Courtenay Boyle had previously fixed. About this period, too, the latter turned his attention to the consolidation of the statutes relating to merchant shipping. In 1890-1 Sir Courtenay served with Lord Rayleigh and Lord Kelvin on the Electrical Standards Committee, and in July, 1898, he was an active member of the committee which, under the chairmanship of Lord Rayleigh, considered the desirability of forming a national physical laboratory. Eighteen months ago Sir Courtenay was called upon to preside over the inter-departmental committee on the expediency of establishing electrical communications between light-houses and the shore, and this committee has not yet finished its labours. One of his last public acts in London was to give evidence before the Parliamentary Committee on Metropolitan Underground Railways. From the inception of the new National Physical Laboratory the late secretary to the Board of Trade took the greatest interest in the progress of the institution, and entertained high hopes of the position it was destined to occupy in English science. In the vexed question of a suitable site for the laboratory he acted with much tact and discernment, and took a prominent part in the long and delicate negotiations with the tramway companies and the Kew and Royal Society authorities, which finally led to the adoption of Bushey House, Hampton Court, as a site, and the settlement of the terms of compensation for the removal of the magnetic apparatus from the Old Deer Park institution, under Dr. Chree. As far, however, as electrical engineers are concerned, Sir Courtenay Boyle will be remembered more for the good work which he done in connection with electric lighting and electric traction regulations. Whenever the industry had so advanced as to require new regulations or the abolition of old ones, the late Permanent Secretary made a practice of holding a conference with electrical engineers representing various interests, and at these conferences the whole matter of the proposed change was thrashed out. Sir Courtenay Boyle's tact in presiding over these conferences was evidenced by the fact that they were always conducted in a businesslike way, all sides having a hearing, and we do not remember any case in which his decision was afterwards cavilled at by any of the parties represented. His last work in this direction was the amendment of the rule which originally gave the consumer power to prevent a complete change over to the higher voltage of an electric lighting undertaking. The decision in this instance was only given a week or two ago. Notwithstanding the great amount of work associated with the post of permanent secretary to the Board of Trade, Sir Courtenay Boyle maintained his general love of sport throughout. In his young days Sir Courtenay made a name for himself both at Charterhouse and Oxford as an excellent cricketer.

Mr. E. W. Parsone.

We regret to record the death, in his fifty-third year, of Mr. E. W. Parsoné, who for the last 30 years has been intimately connected with the submarine telegraph industry. Mr. Parsoné, on leaving the University College School, entered the service of the Great Western Railway Company, and in 1870 joined the staff of the late Sir Charles Bright, and was employed in the laying of the cables of the West India and Panama Telegraph Company. He eventually was engaged on the staff of the India Rubber, Gutta Percha, and Telegraph Works Company, and after being employed in the laying of cables along the French coast and between Marseilles and Algeria, and between Marseilles and Barcelona, he proceeded to the West Coast of South America, and became manager of the first series of submarine cables laid in these waters between Callao, in Peru, and Valparaiso, in Chili. He served with conspicuous ability in this post during the trying times of the war between these two countries, and made many friends among the native and foreign merchants, which friendships have endured until death has carried him away. In the cable steamer "Retriever," Mr. Parsoné surveyed the route for the laying of the cables which connect Salina Cruz in Mexico with Callao in Peru, and are the property of the Central and South American Telegraph Company. Returning to England in 1884, Mr. Parsoné was appointed manager of the West African Telegraph Company, and organised the service on the string of cables connecting the Cape de Verd Islands and the principal settlements on the West Coast of Africa. While on the

Digitized by Google

Congo River he visited Shark Point, and reported to the Royal Geographical Society the locality of one of Diego Cam's beacons, the existence of which was suspected but was unknown to modern geographers. After remaining a few years on the West Coast of Africa, Mr. Parsoné came home and shortly afterwards proceeded to Brazil in connection with the South American Cable Company, of which he was manager and secretary at his death. The deceased had qualifications in connection with submarine telegraphs which are rare among the younger men now that the growth of this great necessity to modern life has called for subdivision of work and specialisation. He knew the business in its electrical, mechanical, and commercial bearings, and was consequently never at a loss in whatever circumstances he found himself. From the personal point of view, his friends have lost a cheery companion full of humour and of goodwill towards his fellow-man. The French Government had conferred on him the decoration of Officier de l'Instruction Publique, and the Government of Portugal had granted a Knight Commandership of the Order of Christ. Mr. Parsoné joined the Institution of Electrical Engineers in 1874, and for the last 20 years has been a full member. He was also a Fellow of the Royal Geographical Societies of London and Lisbon.

Mr. A. H. Roe.

We much regret to have to announce the death of Mr. A. H. Roe, whose appointment as borough electrical engineer of Bury St. Edmunds was chronicled at the beginning of last year. The son of the late Mr. G. Roe, of Bournemouth, the deceased engineer served his apprenticeship in works at Acton. He then entered the service of the P. and O. Steam Navigation Company as a sea-going electrical engineer, and in this way made several voyages to India, China, and Japan. Mr. Roe had completed the electrical equipment of the hospital ship "Coromandel," the vessel which took out Prince Henry of Battenberg on his ill-fated expedition to Ashanti, when he obtained the post of assistant engineer to the Bradford Corporation. He remained there some three years, during which time the electric lighting undertaking made great headway, the system of supply being changed over to the three-wire, a new generating station erected and equipped, electric traction introduced, and many other improvements effected. Mr. Roe may, therefore, be said to have carried exceptional experience with him to Bury St. Edmunds, where, as borough electrical engineer during the past 17 months, he supervised the erection of electrical plant, and most successfully inaugurated the lighting of part of the town by electricity in spite of his failing health. While obtaining a good number of electric light consumers, by his excellent organisation the cost of running the station was kept at a low figure. When the late engineer was appointed there was a very strong opposition to electricity in the town, but, in the words of one of the Gas Committee, Mr. Roe proved so tactful and courteous that since then there has been no opposition to speak of. In evidence of this, we may state that the Corporation have recently applied for a loan of £1,200 for extensions. His early demise at the age of 29 years will be deeply regretted by all those who ever came in contact with him, and is a distinct loss to the profession in which he so ably worked.

FORTHCOMING EVENTS.

FRIDAY, MAY 24.

Royal Institution.—At 9 p.m., Dr. R. T. Glazebrook on "The Aims of the National Physical Laboratory."

TUESDAY, MAY 28.

National Electrical Contractors' Association.—At 2 p.m., meeting at 46, Queen Victoria-street, E.C., for the purpose of forming the above association.

Electro-Harmonic Society.—At 4.30 p.m., annual general meeting at the Institution of Electrical Engineers, 28, Victoria-street, S.W.

THURSDAY, MAY 30.

Institution of Electrical Engineers.—At 8 p.m., annual general meeting at the Society of Arts, John-street, Adelphi, W.C.

Royal Institution.—At 3 p.m., Prof. Dewar on "The Chemistry of Carbons" (Lecture II.)

FRIDAY, MAY 31.

Physical Society. — At 5 p.m., ordinary meeting. Papers: "On a Model which imitates the Behaviour of Dielectrics," by Prof. Fleming, F.R.S., and Mr. A. W. Ashton, B.Sc.; "On the Resistance of Dielectrics and the Effect of an Alternating E.M.F. on the Insulating Properties of Indiarubber," by Mr. Ashton; and "Note on the Electrification of Dielectrics by Mechanical Means," by Mr. Ashton.

The annual dinner of King's College, London, will be held at the Trocadero Restaurant on Monday, June 24, Mr. Justice Byrne in the chair.

ELECTRICAL ENGINEERS (R.E.) VOLUNTEERS.

Regimental Orders.

1. **Non-Commissioned Officers' Instruction.** — Wednesdays, 6.30 p.m.

2. **Recruit Drills.**—Tuesdays and Thursdays, 6.30 and 7.30 p.m.

3. **Oil-Engine Instruction.**—July 4 to 13 and July 11 to 20 camps, Monday, 6.30 p.m.; June 6 to 15 and June 13 to 22, Tuesdays and Thursdays, 6.30 p.m.; July 18 to 27 and Aug. 8 to 17, Wednesday, 6 30 p.m.; Aug. 15 to 24, Fridays, 6.30 p.m.; Royal College of Science and School of Mines party on Tuesday, 4.30 p.m.; Central Technical College party on Tuesday, 5.30 p.m.

4. **Uniforms.**—Issued on Tuesday and Thursday, at 7.30 p.m.

5. **Equipment.**—Issued on Tuesday and Thursday, at 6.30 p.m.

6. **Training, 1901.**—It is requested that all non-commissioned officers and men who can change the date of their training to the weeks commencing July 13 to 20, or July 20 to 27, or who can stay both weeks, should notify the Acting Sergt.-Major at once.

7. **Formal Opening of Headquarters.**—Saturday, June 1, 4 p.m. Tickets of admission, including tea, members of corps, 1s. There are a limited number for friends at 5s. each. Application to be made to the Acting Sergt.-Major.

8. **Cycling Club.**—General meeting at headquarters on Tuesday, May 28, 8.30 p.m.

9. **Woolwich Detachment.**—Drills, recruit and company, every Friday, 8 p.m.

(Signed) R. S. ERSKINE, Major, O.C.E.E. (R.E.) Vols.
C. T. RUSE, Acting Sergt.-Major.

NEW COMPANIES.

The following new companies have been registered since our last issue:

Electrical Productions, Limited.—Capital, £3,000. Object: to carry on the business of manufacturers of and dealers in wires, cables and lines of all kinds, electricians, mechanical, gas, and general engineers, etc.

Desolle Electroplating Company, Limited.—Capital. £70,000. Object: to acquire certain patents of M. E. L. Desolle, of Fontenay Bois, France, chemical engineer, relating to electroplating, and to carry on the businesses of mechanical, electrical, sanitary, and general engineers, etc.

Chadwick, Son, and Clarke, Limited. — Capital, £3,000. Object: to acquire the business carried on at the Princes Bridge Ironworks, Salford, Lancashire, as John Chadwick, Son, and Clarke, to adopt an agreement with James A. T. Clarke, and to carry on the business of engineers, electricians, providers of electric light and power, etc.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street London, E C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered price 8s. 6d.

SCRAP.

A nice short word of five letters, conveying a suggestion that may be beneficial or result in the loss—to someone else, of course—to the extent of thousands of pounds. The little investigation that we have been able to make into the habits and idiosyncrasies of those who call, not "Wolf, wolf," but "Scrap, scrap," tends to make us believe they are about the last people in the world to follow their own advice. The wholesale suggestion to scrap comes from sellers, who naturally do not care a fig for the financial position of the buyers provided they get the money due for sales. Then when advice is not thought to be weighty enough, it is interlarded with tales of what the Americans do. It is always America! There, we are informed, the financial princes and parvenues alike scrap directly someone puts something better on the market. They are a happy-go-lucky race, according to the views of the wiseacres, and money is no object. Neither is it with certain ladies who buy dresses and forget to pay for them. But, joking aside, is there not a time to scrap, and a time not to scrap? Some of us may recollect the introduction of three-cylinder locomotives. According to those who favoured this type, they were far and away better than what had gone before, and if the favourers of indiscriminate scrapping are to be believed, all the old engines ought straightway to have gone to the scrap heap. Yet Mr. Webb, the able locomotive engineer to the London and North-Western Railway, did not scrap his other engines, nor did any other locomotive engineer do so. Perhaps it will now be urged that time has proved the three-cylinder not to be so immeasurably superior to its predecessor as its early advocates supposed it to be. Time may say the same with regard to some of the electrical apparatus which it is said ought to replace that consigned to the scrap heap. Sellers have to sell, and their words are not always words of wisdom, but rather of the character of pushing advertisements. Their blandishments are calculated to catch the unwary, and success means profit. Is it possible to say when it pays to scrap and when it pays to retain apparatus? We imagine the whole problem is one of simple arithmetic. Assume that a purchaser buys the best piece of apparatus known at the time of purchase. Assume, also, that he is a business man, and calculates that his profit by the use of this particular piece of apparatus will be sufficient to enable him to live in competition with his neighbours. Of course, he allows each year enough for depreciation, so that when the apparatus in the ordinary course of nature ceases to exist, its capital charge in the books also ceases to exist. Say depreciation is 10 per cent., giving the apparatus a ten years' life. One thing we should like to mention as an aside. It is that a business man cannot always depreciate up to the standard prescribed by "abstract" argument. There is never an absolute certainty of making a profit sufficient to do all that the abstract argument says ought to be done. If the profit is insufficient, what then? Two courses are open: one is to worry along over a longer life, the other is to

Digitized by Google

make a dead loss. Either way is bad. In the former case possibly the old apparatus has to compete against newer development; in the latter case another business man, firm, or company goes to Carey-street. Just as there are two courses open in the case assumed, so there are two conditions to be considered when the question of scrapping arises. First, has the man, firm, or company, the capital at call to replace the scrap? If the capital is not there, scrapping is impossible. Secondly, will the new apparatus enable the user to obtain the extra profit required by the extra capital expended; for the new machinery stands capitalised in the books, not at the amount of its cost, but at that amount plus the capital at which the machinery scrapped stood in the books. It is very easy to say "scrap," but sovereigns do not grow like mushrooms, and scrapping costs money. No doubt it is hard for a man to invest his whole capital in a business only to find the tools and machinery installed getting obsolete before they have earned enough to enable him to replace them. There is, of course, another way of looking at this thing. There always is; and no doubt some people will argue that when scrapping is necessary capital should be forthcoming. This would mean a reserve of capital, which is not economic so far as a business man is concerned; hence we conclude that indiscriminate scrapping is neither possible nor economical.

REVIEWS.

Conduit Wiring and Erection. By L. M. WATERHOUSE. S. Rentell and Co., Limited, 2, Exeter-street. Price 2s.

The two great faults we have to find with this book are, first of all, the incompleteness of its title and, next, its price. It should be called the "Simplex System of Conduit Wiring," and it should be given away free by the makers of these conduits. In the first page of the book the author adds after the title, "Conduit Wiring and Erection," the following words: "With special reference to the Simplex system of steel conduits." We have looked through the 80 odd pages of this book in a casual way without seeing any reference whatever to any other kind of conduits. The illustrations also, when not actually taken from the catalogue of the company supplying these conduits, are made from photographs of installations carried out on the Simplex system. Again, excepting on those pages which deal with the gauges and capacities of copper conductors, we do not think there is a single page in which the Simplex system of conduits is not either directly mentioned or referred to. While we agree that the author has given a limited amount of independent advice as to the running of conduits for electric light wires, we do not think there is any excuse for asking an electrical engineer to pay 2s. for a book which is really an advertisement of one class of conduit only. We do not mean by this that the Simplex conduit system is not a valuable one to electrical contractors, but rather that any praise bestowed on it by Mr. L. M. Waterhouse would be much more valuable if at the same time he placed before his readers the advantages and disadvantages of the rival systems of conduits which are in the market.

POWER BILLS.

The Shannon Water and Electric Power Bill.

This Bill has passed the Select Committee of the House of Commons presided over by Mr. Arthur Elliott with but slight opposition. In the West of Ireland there is no coal supply, and the proposition under this Bill is to utilise the waters of the River Shannon to generate the electrical energy. For this purpose the promoters intend to construct a canal, with an intake from the Shannon at a point a few miles from Limerick, 2½ miles in length, to Cloonlara, where the power-house will be situate, the fall at this point being 40ft. At first it is proposed to equip this station to produce 5,000 h.p., which eventually could be extended to 8,000 h.p. After passing the power-house, the water, according to the present proposals, will be reconveyed to the Shannon by means a tail-race two miles in length. Under this scheme only four miles of the river will be interfered with, and on such occasions as it will be found impossible to take water from the river, an auxiliary steam apparatus, which it is proposed to set up, will enable the company to fulfil their obligations to their customers. The area proposed to be supplied extends 30 miles from the power-house, and the price to be charged for electric power will vary from a maximum of 5d. to a minimum of 2d. per unit. It is proposed to supply the Corporation of Limerick, however, at the fixed price of 2d. per unit. The proposed capital of the company is £360,000, with borrowing powers of £180,000. The estimates prepared show the cost of the works to be £265,000, and the working plant £75,000, making a total of £240,000. The Bill also asked for general powers to supply electricity not only for motive purposes, but for general lighting. To this the late Sir Courtenay Boyle, on behalf of the Board of Trade, took exception before the Select Committee. He pointed out that the proposals were contrary to adopted policy, and that lighting powers should only be allowed for special districts and not wholesale. The promoters then asked to be put in a position to grant powers to other persons. That, again, was *ultra vires*. Further, there was no provision in the Bill to supply on reasonable demand, as in the Bills of last year, and there was no sliding scale proposed. If the water power were abandoned, there was nothing in the Bill to show that the other powers of the promoters ceased. In deciding that the preamble of the Bill was proved, the chairman directed clauses to be brought up to satisfy the wishes of the Board of Trade. During the course of the enquiry a suggestion was made on behalf of the Treasury that payment should be made for the water abstracted from the Shannon, but with this the committee expressed itself not in favour. Mr. Fraser, C.E., is the engineer to the scheme.

The Cleveland and Durham Power Bill.

In further reference to the above Bill, we neglected in our last issue to mention the name of Mr. A. A. Campbell Swinton, of 66, Victoria-street, S.W., as engineer to the scheme, in conjunction with those of Messrs. Bramwell and Harris, of Great George-street.

THE COMING VISIT OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO BERLIN.

The Cable Works of the Allgemeine Elektricitats-Gesellschaft.

One of the most attractive visits which will be paid by the Institution of Electrical Engineers will be that to the cable works of the Allgemeine Elektricitäts-Gesellschaft. These fine works are pleasantly situated on the banks of the Spree at Oberschöneweide, a village about 10 miles to the east of Berlin; and by the courtesy of the directors of the company a boat will be placed at the disposal of the party, so that the journey may be made by water, which, should the weather be favourable, will be a much more agreeable method of travelling than by rail. If further example were needed to illustrate the rapid growth of the electrical industry on the Continent, it could not be better found than in the new cable works of the Allgemeine Elektricitäts-Gesellschaft, the equipment and organisation of which are model in every respect, and cannot fail to leave an impression upon the visitor. The

Digitized by Google

annual output of copper in the form of cables has increased between the years 1890-1900 from 112 tons to 9,000 tons.

Up to the end of the year 1897 the manufacture of cables and insulating material was carried out in the Ackerstrasse, in the building known at present as the apparatus factory. The accommodation being insufficient to meet with the demand, however, the directors acquired a site at Oberschöneweide, where the building of the new factory

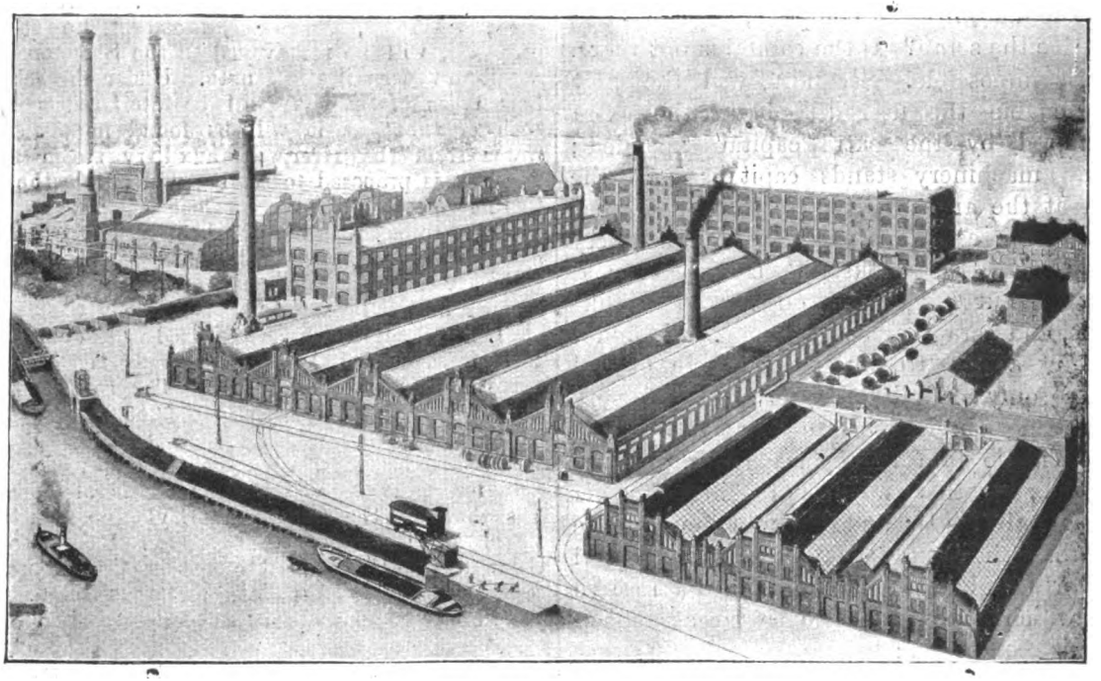

FIG. 1.—The Cable Works of the Allgemeine Elektricitäts-Gesellschaft, Oberschoneweide.

was commenced in 1896. The site chosen had the special advantage that, being alongside the river, it was possible to bring all raw materials by water to the works, the river being navigable right away to Hamburg. A railway siding and branch line were constructed to connect the works with the neighbouring railway, and specially-built wagons provided for the carriage of heavy drums of cable. A complete system of lines extends throughout the works and goods yard, and several electric locomotives and cranes are in use for dealing with the outgoing and incoming materials. The works were completed towards the close of the year 1897, and the whole of the cable machinery was removed from the Ackerstrasse, and the factory put into operation in the short time of 14 days. The buildings are illustrated in Fig. 1. To facilitate communication with the passenger station at Neider Schöneweide, which is on the opposite bank of the river, the Allgemeine Elektricitäts-Gesellschaft, in conjunction with another firm, built the handsome bridge which now spans the Spree. It is constructed of wrought iron throughout in three spans, the centre one being 90 yards long, and the two outers 50 yards. The bridge is open to general traffic, which has, of course, greatly increased owing to the new dwellings which have sprung up since the cable works were started.

The ground occupied by the cable works amounts to 100,000 square yards. The different manufactures are carried on in five separate buildings, and include the copper and metal-working, cable, wire, indiarubber, and micanite departments, as well as a large cable machinery repairing shop, foundry, and woodworking shop for the manufacture of cable drums, etc.

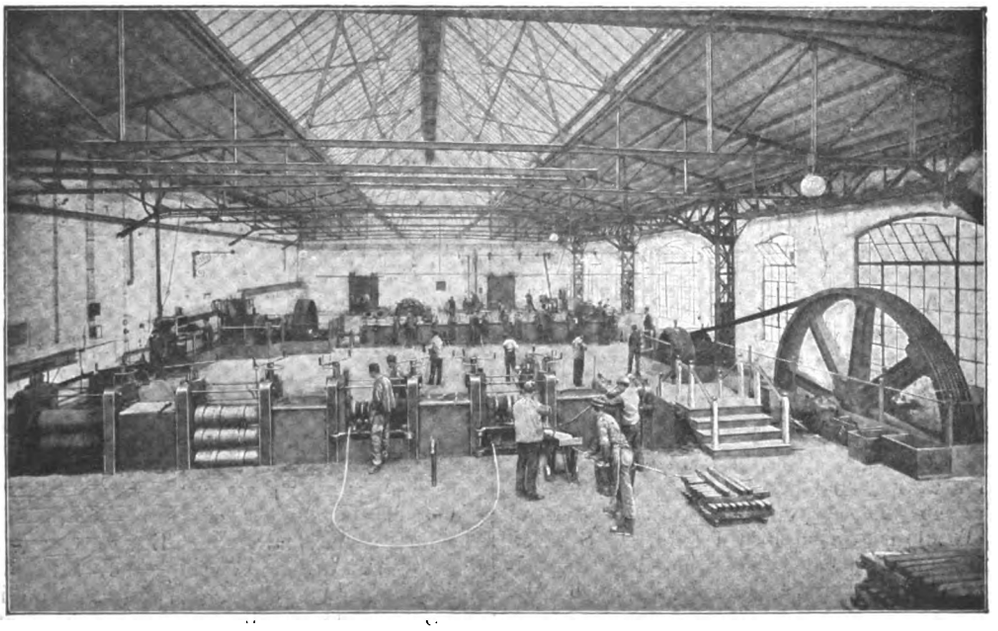

FIG. 2.—Copper Rolling Mills, Oberschoneweide.

The machines and tools in all departments are driven by separate three-phase electric motors, of which there are nearly 600 in use. The total power consumed amounts to 3,000 h.p., which is obtained from the neighbouring central station of the Berliner Elektricitäts Werke at a tension of 6,000 volts. The absence of a power station is a noteworthy feature in these works. The underground three-phase mains are brought into a gallery at the end of the wire-drawing department, where the whole of the apparatus

Digitized by Google

for controlling the driving of the factory is placed, including the step-down transformers and the motor-generators which convert the three-phase current into continuous current for the working of the cranes.

The copper and metal-working department is devoted to the rolling, drawing, and annealing of the various wires, bars, etc. The heated bars coming from the ovens are 1m. long and about 9cm. square. Fig. 2 shows the rolling

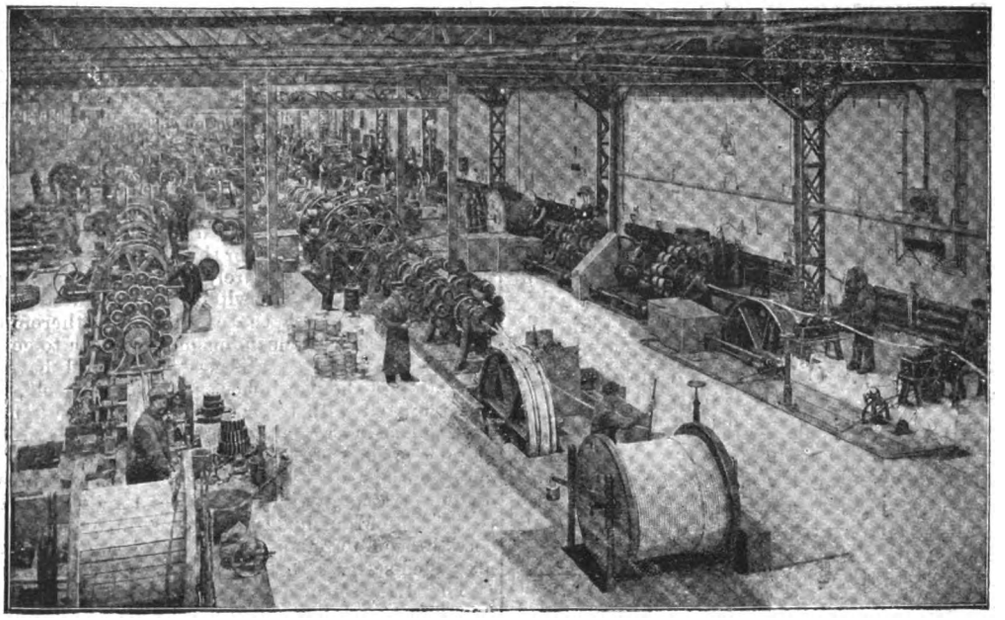

Fig. 3.—High-Tension Cable Department, Oberschoneweide.

machines, the three being driven by a 600-h.p. three-phase motor. The bars are passed rapidly backwards and forwards through the rolls, and in three minutes their diameter is reduced to 6mm. and their length increased to 260m. This wire is then passed through drawing machines of the Allgemeine Electricitäts-Gesellschaft's special design, and its section reduced to any desired value. The diameter of the smallest wire drawn by these machines is about 2mm.; the finer wires are drawn in a special department. They are made by passing the wire through diamond dies drilled to the necessary diameter. In this manner uniformity in the section of even the smallest wire is ensured. On one of these drawing machines several diamond dies of different sizes are put one above the other, so that wires on the same machine diminish their diameter by passing through the dies in succession. The smallest diameter drawn is 0·05 mm. Not only round wires but bars of various sections are drawn in this department, such as commutator segments, 'bus bars for switchboards, and overhead trolley wires. Electrolytic copper of the highest conductivity is generally used. The large increase in the cost of copper, however, has caused aluminium to be used as a substitute for many purposes. Aluminium has not so high a specific conductivity as copper, but weight for weight it has about double the conductivity. The Allgemeine Elektricitäts-Gesellschaft are now manufacturing large quantities of aluminium wire.

Every variety of cable and wires can be turned out to suit both English and foreign specifications, so complete is the equipment with which the company are in possession. A special feature is made of lead-sheathed cables for lighting and power-transmission purposes which are suitable for working tensions up to more than 20,000 volts. These high

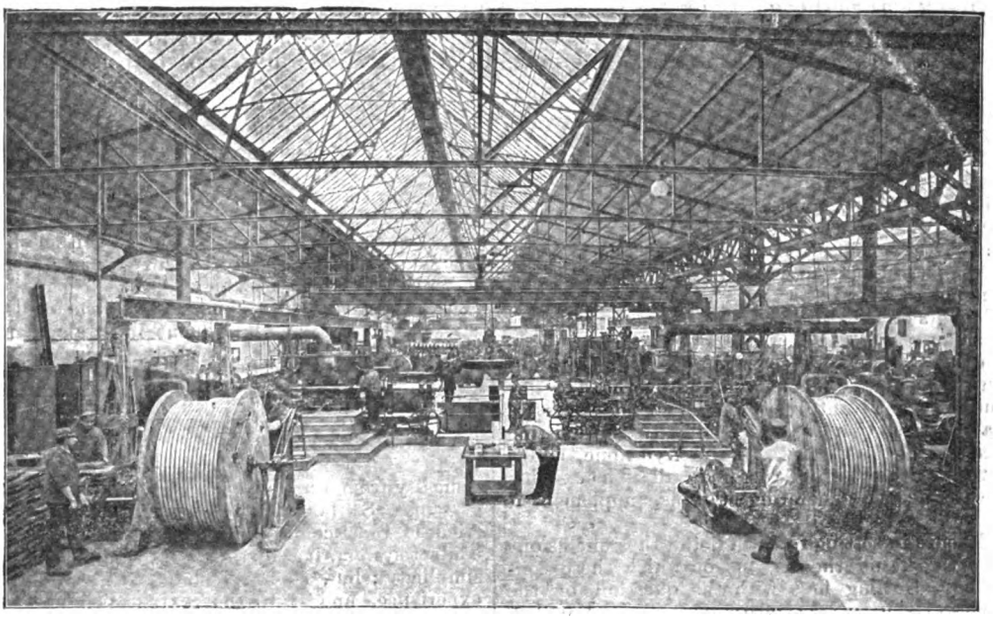

Fig. 4.—Lead-Sheathing Department, Oberschoneweide.

tension cables (Fig. 3) are subjected to a trial test of 40,000 volts. The insulation used for ordinary lead-covered cables consists of, first, a layer of jute, from which, when completed, the moisture is extracted by vacuum drying presses. The vacuum drying method is specially interesting, being a great advance on the old-fashioned methods of baking. The cables are coiled up into baskets, each drying oven having room for four of these. The ovens are heated with steam-coils, and the air carefully exhausted from them

Digitized by Google

after the cables are placed within. The vacuum gauge on the outside of the ovens affords a ready indication as to when the jute covering is thoroughly dry. After drying the cable is passed through a bath of resinous insulating compound, and from thence into the lead presses, where it receives a seamless sheathing. This lead covering is put on by hydraulic pressure. The cable after leaving the insulating compound is drawn through the interior of a patrix or conical-shaped ring, which is surrounded by a matrix resting against the end of the lead chamber. The half-melted lead is forced down through the space between the matrix and patrix, and forms a seamless sheath over the cable as it is drawn through the press. By adjusting the distance between these two dies, the thickness of the sheathing can be varied. These presses (Fig. 4) have been found to give great satisfaction, the sheathing process being continuous as long as the press is fed with lead, and thus cables of any length can be given a jointless cover. Cables manufactured in this way are ready for use without any additional treatment, but frequently receive a further protection against external abrasion. They are first covered with a layer of jute, impregnated and dusted with French chalk, and armoured by a double layer of hoop iron or iron wire, and finally asphalted as a protection against moisture. Cables for working tensions of from 5,000 to 10,000 volts are insulated first with a layer of impregnated jute, then with a mantle of rubber and a taping of paper, after which comes the lead sheathing. Cables for still higher tensions receive, instead of the jute, a sheathing of rubber, and over this a specially-prepared insulating material of such a nature that a piece 1mm. thick will withstand a pressure of 50,000 volts without injury. Cables insulated with this material can be used with security for working pressures of 25,000 volts. Lead-covered cables can be made with a single core or with two or three cores, twisted or concentric.

(To be continued.)

ELECTRIC TRAMWAYS FOR LEICESTER.

The following is the full text of the report of Mr. E. Manville, M.I.C.E., on the proposed electric tramways for Leicester. This report has been adopted, and Mr. Manville appointed consulting electrical engineer for the work. The expert's review of the advantages of the various systems will be of great interest to electrical engineers. The report is addressed to James Bell, Esq., the town clerk of Leicester, and reads as follows:

In accordance with the instructions contained in your letters of Feb. 21 and 25 and March 8, I have very carefully considered the several questions which have been laid before me, with the object of reporting thereon; and have conferred with your Tramways Committee, with the individual members of your Corporation who have given special consideration to the matters, with your gas and electric light engineer (Mr. Colson), and with your borough engineer (Mr. Mawbey).

The principal points on which I have now the honour to report to you may be summarised as follows: (1) the relative advantages, in the case of Leicester, of the underground conduit systems, the surface-contact systems, and the overhead trolley systems; (2) the relative advantages of an independent central power station, a power station in connection with the existing Corporation gas and electric light works at Aylestone, and a combination of the various dust destructor installations existing in the borough with electric generating stations, supplemented by coal-fired boilers.

I have now pleasure in setting forth in detail the conclusions at which I have arrived, and the reasons on which these conclusions are based. Dealing first with the question of the relative advantages of the surface-contact systems, the underground conduit systems, and the overhead trolley systems, I have considered the matter under the two heads of safety and reliability in working and capital cost.

Surface-Contact Systems.

Your committee especially brought to my notice four surface-contact systems. I have supplemented my own knowledge by consultation with those specially interested in each such system. The systems were as follows: (1) the Lane electromagnetic; (2) the British Schuckert; (3) the Union Electricitäts-Gesellschaft; (4) the Dolter.

Both the systems of the British Schuckert Company and of the Union Electricitäts-Gesellschaft consist essentially of contact plates located at somewhat frequent intervals in the centre of each track, but having no electrical or magnetic apparatus attached thereto, the actuating apparatus being in groups situated in chambers formed beneath the sidewalk at infrequent intervals. The chief advantage claimed for these systems is that the apparatus putting the contact plates in circuit with the conductors carrying the electric current are not situated beneath the road surface, but in positions in which they can be easily inspected and properly maintained, and are, therefore, less liable to derangement than other systems involving the switches or controlling apparatus being placed in the roadway beneath the individual contact plates. Both these systems are at work to a limited extent on the Continent of Europe, but, in common with the other surface-contact systems, have never been tried on a practical scale in this country, and must therefore, to some extent, be regarded as still in the experimental stage.

The Dolter system consists of a surface-contact plate or block—as in the above two cases—installed at moderately frequently intervals along the track, each surface-contact plate having beneath it a magnetic switch, which places the same in circuit with the insulated electrical conductor carrying the current. The advantage claimed for this system is that the switch beneath the road surface is purely magnetic, and magnetism in the magnet portion of the switch being induced by the collecting bar carried beneath the car, involving therefore no windings round the subterranean magnetic switch to get out of order; and from a model of this system which I have inspected, the operation of these switches seems to be reliable, and the system, as compared with other surface-contact systems, undoubtedly has the advantage of extreme simplicity, and less liability to derangement, than others in which wire-wound switches form an essential part. This system is at present in use to a limited extent on a tramway in Paris, and I am informed that the consent of the Municipality has been obtained to its extension in substitution for another system at present in use on a more extended scale.

The Lane electromagnetic surface-contact system presents many features of originality. It consists essentially of a gas-tight metallic conduit, in which is contained a flexible magnetic conductor, resting upon porcelain insulated bridges, placed at frequent intervals within this conduit. On the top of the conduit, and brought up to a level with the road surface, are the regular surface-contact plates employed in all these systems, so arranged in this case that when the magnetic conductor is brought towards the top of the conduit, it places itself in contact with the surface-contact plates above. The car carries a short collector, which is made permanently magnetic—as in the case of the Dolter system—by magnetising coils, energised by the current derived from the conductor or from a separate small battery of accumulators carried upon the car. As the car travels over the surface of the contact plates, they are successively magnetised by the collecting bar, and pull up the magnetic conductor into contact with them, the collector being so arranged that, as it passes on, the poles of the surface-contact plates are reversed as the collector leaves them, thus not only releasing the magnetic conductor, but repelling it, thereby ensuring disconnection of the circuit when the car has passed. To ensure the magnetic conductor and the projection of the contact plate with which it makes contact remaining unoxidised at the breaking of the circuit, when sparking might occur, the whole of the conduit is denuded of oxygen, and filled with some gas, in the presence of which neither the magnetic conductor nor the contact plates will oxidise; and in the case of a street tramway it is proposed that coal gas should be used for the purpose. This system involves the contact plates being placed at much more frequent intervals than is common to the other systems of surface contact—viz., at intervals of about 8in.—as compared with a distance of about 10ft. in the case of most other systems. This, in itself, presents some advantage, as the length of the collector is consequently shorter, and less mechanical difficulty arises in connection with the irregularity of the surface of the paving—an element of considerable difficulty from a maintenance point of view with most contact systems. So far as I am aware, this system has never been tried in practice in this country or elsewhere. As a surface-contact system, it is distinctly attractive, in view of its extreme simplicity; but, so far, it has not stood the test of practical experience, and is to that extent behind the other systems mentioned.

In addition to these four systems specifically mentioned by members of your Council, there are many other surface-contact systems, some of which have been tried in practice. One which was inspected by the sub-committee of your Tramways Committee is the Diatto system, which is now being used on a somewhat extensive scale in Paris, and from what I can gather as to the practical results of this system, these are not altogether encouraging for its adoption in this country. It must be recollected that there is probably no climate so trying to the use of a surface-contact system as that prevailing in this country owing to its extreme humidity, and even if any of these systems worked successfully in other climates it does not by any means

Digitized by Google

follow that such a system would give satisfaction in this country on that account.

Beyond the difficulties that might be apprehended owing to the prevailing humidity in this country, there are further risks connected with the possibilities of a surface-contact plate being left in circuit with the live conductor after the car has passed from over it. Your Council will readily appreciate that all moving switches, however simple they may be in their construction, are liable to failure in action on some occasions. If this failure prevented the contact plate being put into circuit with the live conductor no serious consequences would follow, and but little inconvenience would be experienced in the supply of current to the car; but, on the other hand, if the failure involved the contact plate remaining in circuit with the live conductor after the car had passed, very serious consequences would be likely to follow. It is, for instance, certain that horses or cattle of any description treading upon the surface-contact plate would be seriously hurt, and probably killed, and so far as human beings are concerned, although the consequences are likely to be less fatal, the shocks received by them might be of a serious description, especially in the case of aged persons or those who have a weak constitution; and it is a matter of common knowledge that a good many accidents of the character of those referred to above have occurred in Paris in connection with one of the systems which have been there installed.

In connection with the working of this particular system of surface contacts an interesting report has been issued upon the subject by the Paris Municipal Council, the French Ministry of Public Works, and other public bodies in Paris concerned in the safety of the streets, and published in *L'Industrie Electrique*, from which I gather that, as a result of a letter received from the Prefect of Police, showing that during the period extending from June 15, 1900, to Feb. 20 last no less than 120 accidents had taken place, of which 58, or practically half, occurred in January last—that is to say, during the snowy period—the French Minister of Public Works instructed the Comite d'Exploitation Technique des Chemins de Fer (Committee on the Technical Working of Railways) to enquire into the inconveniences and dangers which may appertain to the Diatto system. This committee reported that the accidents that had taken place were due to: (1) Insufficient drainage of the surface contacts and conduits, causing shunt currents. (2) To the action of the special contacts fixed fore and aft to the motor tramcars at the moment these contacts pass over the surface contacts. (3) In order to give stability to the latter, they have been supported by two metallic cross-pieces joining the tram-rails, an arrangement which is very bad from the point of view of the insulation of the surface contacts, and one which has been attended, when the tramlines have been sprinkled with salt after a fall of snow, with most unfortunate results. (4) The sparking which occurs each time the working of the surface contact is not perfectly regular gives rise to a formation of a conducting deposit of carbon, due to the combustion of the material of which the surface-contact box is made. (5) Finally, the committee reported that to the bad insulation of the cables, apart from the insufficient drainage of the conduits, many of the accidents are to be attributed. This insufficient insulation, while dangerous to public traffic, is not less so to pipes, buildings, and anything of metallic construction laying near to the tramway lines. Strict precautions are imposed in this regard on trolley tramway installations, and the committee consider that similar precautions should not be overlooked in the case of surface-contact lines, in which perfect insulation is much more difficult of attainment.

In December last the Prefecture of Police issued instructions to the tramway companies that all the surface contacts must be visited daily, and a report sent to the Prefecture within the next 24 hours on the results of the inspection, that the special contacts on the cars must be temporarily suppressed, and that at various points on the lines means of draining the conduits be laid down. An arrangement was also arrived at between the tramway companies and the Street Cleaning Committee of Paris, that the tramway lines should not be sprinkled with salt after a fall of snow. In their report, the committee, without expressing any opinion on the merits of the Diatto system, for or against, approve the action of the Prefecture of Police, and recommend (1) that the tramway companies be requested to establish sufficient space between the surface contacts and the cross-pieces above referred to; (2) to take steps, on the one hand, to suppress the formation of carbon deposits inside the surface contacts, and, on the other, to improve the defective insulation of the conduits; and (3) that the paving of the road around the surface contacts should always be kept in excellent condition. As a result of the report the Paris Municipal Council has passed a resolution calling upon the tramway companies to carry out the improvements outlined in the report above alluded to before Oct. 1 next.

There is no doubt that the surface-contact systems are very attractive, owing to their low cost of construction, as compared with an open-conduit system, and to the absence of a slot in the roadway, and, as compared with the overhead system, surface-contact systems are again attractive by reason of the entire absence of the standards and overhead gear inseparable from such a system, although, in regard to cost, the surface-contact system is somewhat more costly than the overhead system. I have given much consideration to the desirability of your adopting one or other of these systems; but I feel that, in the absence of practical experience of any of them in this country, it would be impossible for me to advise you to take upon yourselves the burden of an experimental demonstration which might end in the waste of public money, and would, in that case at all events, bring discredit upon your electrical tramway system at its inception, from which it might take a long time to recover, beyond which there is the more serious consideration of a possible result, involving, it might be, serious injury, or even fatal accidents, arising from failure of a part of any of the numerous circuit-making devices common to all such systems. At a later stage in this report I shall have some further remarks to make in relation to the possibility of installing a surface-contact system at some future period, but for the moment I would pass on from the consideration of this subject, and deal with the other methods of distribution of electrical energy to the cars.

Open-Conduit Systems.

Of open-conduit systems it may safely be said that they can all — in a well-drained town like Leicester — be depended upon, if properly designed, for reliable working, facility of maintenance, and immunity from danger; and the only objections which can be urged against them, as compared with the surface contact and overhead trolley systems, are the presence of a third rail—or pair of rails—breaking up the pavement, involving increased maintenance thereof, and the undoubtedly greater capital expenditure necessitated in the installation of such a system. I do not think it is necessary for me to enter at length into the consideration of the first objection, which is one which your Council themselves will be able to fully appreciate and duly recognise at its proper value; and with regard to the question of capital cost, I can more conveniently deal with this later on, in comparison with the cost of the overhead trolley system; and I am of opinion that if considerations of capital cost and somewhat higher maintenance in regard to the paving, together with the added obstruction of additional metals in the road surface, did not enter into your consideration, there can be little doubt that in the present state of experience, the conduit system would present advantages which would probably induce you to adopt it in preference to any system of surface contact.

Overhead Trolley Systems.

As your Council are well aware, the overhead trolley system is—as compared with other systems—almost universal. It has, as a rule, given almost unqualified satisfaction in use, and it is probably not too much to say that, although in a few cases accidents have occurred in the use of this system, these can be traced either to inefficient or faulty construction, which might have been avoided, or to gross carelessness, which cannot be wholly guarded against in any system of mechanical traction. It has sometimes been urged against the overhead trolley system that the use of the rails as the return circuit for the current might lead to the destruction of water and gas pipes and other metallic substances in the road, due to electrolytic action. It is hardly necessary, however, to point out that if the return system is properly designed, so that the differences of potential along the rails are kept well within the limit stipulated for by the Board of Trade, no results of this description need be feared; and in those cases in the United States where great destruction of pipes has taken place, this has invariably been due to an utter disregard of the above-mentioned conditions, which are essential to safe working in this respect. At one time the overhead trolley system did not find favour in this country for purely æsthetic considerations, with the result that more care has been taken to render the appearance of the overhead construction less obtrusive and objectionable than was formerly the case; and to-day, in this country, as your Council are aware, most of the principal cities having a regard for the appearance of their streets are adopting this method, not to mention Continental cities, where æsthetic considerations are generally considered even to a greater extent than in this country. This question of æsthetic consideration is one which is, perhaps, to some extent, outside the scope of an engineer's report; and when I have laid before you the financial conclusions at which I have arrived, it will be a matter for the consideration of your Council whether the æsthetic advantages of the conduit system compared with the overhead system are commensurate with the greatly-increased capital expenditure involved therein. The æsthetic question—apart from technical considerations—is one rather of individual opinion than of expert judgment; and your Council will doubtless, in dealing with this side of the question, give due consideration to the opinions formed and the views expressed by their sub-committee, who have made such an exhaustive examination of the various types of overhead construction installed in the numerous cities in this country and abroad, which

Digitized by Google

they have specially visited for the purpose of forming a judgment; and I feel that it would be presumptuous on my part to express a merely individual opinion on this subject, which is entirely remote from any question of technical consideration; and I will therefore merely confine myself to saying that there are, in my judgment, no conditions in Leicester which make the introduction of the overhead trolley system less applicable than in the other important cities and towns of England which have already adopted it.

Before dealing with the question of the comparative cost of the overhead and conduit systems, I think it necessary to point out that there are special conditions in Leicester which make the introduction of a conduit system somewhat difficult—namely, the existence of at least three bridges carrying main roads over the railways and sidings of the Midland Railway Company, where the available depth from the surface of the road to the upper surface of the bridge construction is at present insufficient to admit of the construction of a conduit. I believe it would be possible in all these cases to so alter the form of the bridge decking as to enable a conduit to be constructed, and consequently the difficulty will probably be mainly represented by cost, provided either the consent of the railway company or compulsory powers can be obtained to enable such alterations to be carried out. Apart from this consideration, which is one which would require to be gone into in very considerable detail before absolutely deciding on a conduit system, should the Council otherwise favour this method of traction, I propose dealing now with the comparative cost of the overhead and conduit systems. In order to arrive at the expenditure your Council are likely to incur in the construction of either one of these systems, I have thought it desirable to base my estimates not only on the reconstruction of the existing tramways and the construction of those extensions already authorised by your Council, but I have included some further extensions which it appears are likely to be required in the immediate future, and the following is a schedule of the routes showing the approximate lengths thereof:

	m.	c
Existing lines—		
Belgrave road route	1	63
London-road route	2	2
Humberstone gate route	1	49
Aylestone route	1	75
Church-gate route	1	2
Total	8	31
Extensions of existing lines—		
Belgrave-road route	0	60
Loop line along Bedford street	0	42
London-road route	0	46
Humberstone gate route	0	38
Aylestone-road route	0	58
Bowling Green-street and Welford-place route	0	15
Church gate route	0	38
Total	3	57
Additional new lines—		
Narborough road route	1	54
Hinckley-road route	1	8
Fosse-road route	0	70
Great Central street route	0	26
Melton road route	1	10
St. Peter's-road, etc., route	1	52
Highfield-street line	0	18
Evington-road route	0	50
Melbourne-road, etc., route	0	62
Welford-road route	1	62
Clarendon Park-road route	0	57
Groby-road route	0	70
Cavendish road, etc., route	0	68
Belvoir-street route	0	13
Park-road (including Queen's-road) route	1	0
Evington-lane route	0	77
St. Saviour's road route	0	75
Upperton-road and Walnut-street route	0	61
Total	16	33

From the above table it will be seen that the total length of the whole of the tramways in contemplation amounts to about 28½ miles, of which 19½ miles are double line and nine miles single line, the figure for double line being, of course, inclusive of an allowance for passing places on the single-line routes, which I have had more or less to approximate, but which may be taken as sufficiently accurate for the purposes of this comparison.

I have gone very carefully into the estimates of cost of the construction of these tramways—both on the overhead and the conduit system—including the whole of the electrical equipment in the roadway. In dealing with the cost of the construction adapted for overhead construction, I have based my figures on the very best modern type of construction. As regards the conduit system, there is not so much data available as in regard to the overhead system. The experience in this country in regard to the conduit system is practically nil, and the figures available from the experience obtained either in America or on Continent are scarcely applicable in this country. In this connection I would point out that there appears to be a very great divergence of opinion amongst those engineers who have carried out conduit systems abroad as to the proper size of the conduit and in respect to the general details of the design. The figures available from foreign experience as to the cost of conduits are so excessive as almost entirely to preclude the consideration of the use of this system in this country, excepting in the largest cities, and there only where the traffic is so extensive as to practically make the question of first capital cost of but little moment. I am, however, myself disposed to think that a thoroughly reliable and efficient conduit system can be constructed at a much more moderate price than has heretofore been estimated on the basis of foreign experience, and I have thought it only right in comparing the two systems of overhead and conduit traction to thoroughly analyse the prices and quantities on which these foreign estimates are based, and to adapt and modify them by my experience of English prices and conditions; and I think that the figures which I have arrived at, while being sufficient, may at the same time be taken as the very lowest estimate of what a reliable and efficient conduit system could be constructed for in this country. I append to this report a cross-section showing the general type of conduit on which my estimates are based, and I would state that I have had occasion, in connection with cable and other conduits, to very carefully test and experiment on the necessary strength of yokes or castings for such purposes when subjected to the most extreme conditions of street traffic, such as those designed by my firm for Birmingham and Edinburgh, and I therefore speak with some confidence as to the suitability of the particular type of conduit on which my estimates are based. With these introductory remarks, I beg to submit the following figures at which I have arrived:

Conduit System.	£
Cost of constructing nine miles of single line of tramway complete, including conduit, together with the electrical equipment therein, and allowing for the points and crossings at junctions, but exclusive of feeders (or, say, £10,786 per mile)	97,077
Cost of constructing 19½ miles of double line of tramway complete, including conduit, together with the electrical equipment therein, and allowing for the points and crossings, and also a sufficient number of cross-over roads, but exclusive of feeders (or, say, £22 941 per mile)	447,342
	544,419
Add 10 per cent. for engineering and contingencies	54 442
	£598 861
Estimated cost of alterations to water-mains, sewers, manholes hydrants, bridges, etc. (but exclusive of alterations to the two Midland main-line bridges at London-road and Welford-road) as estimated by the borough and water engineers, say	46,064
	£644 925
Overhead Trolley System.	£
Cost of constructing nine miles of single line of tramway complete, including points and crossings, bonding, and overhead electrical trolley equipment, but exclusive of feeders (or, say, £6,079 per mile)	54,71
Cost of constructing 19½ miles of double line of tramway complete, including points and crossings, cross-over roads, bonding, and overhead electrical trolley equipment, but exclusive of feeders (or, say, £11,148 per mile)	217 385
	272,096
Add 10 per cent. for engineering and contingencies	27,210
	£299,306
Difference in cost on the complete system between overhead and conduit systems, exclusive of feeders	£345,619

These figures, as above stated, are exclusive of the cost of feeders, which, as shown hereafter, will cost considerably more in the case of the conduit system than in the case of the overhead trolley system, owing to the necessity in the former case of having an insulated return as against the uninsulated rail return in the overhead system, and involving in consequence an extra amount of feeders of larger section. I do not propose, however, at this stage to deal with this matter in detail, as the cost of feeders in both cases must, to some extent, be dependent on the situation of the generating station, and is dealt with under that heading.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

379. What is considered the best form of gearing on electrically-driven pumps for silent running and durability? Has chain gear met with any success?—J. R.

380. Give a sketch and discuss the merits and demerits of an earthing panel for the middle wire of a three-wire continuous system of distribution.—S. D. S.

ANSWERS.

Question No. 374.—I wish to have a motor driven by a dynamo at a short distance apart, but the motor to correspond in speed *exactly* to that of dynamo, however varied the speed of the dynamo may be. What peculiarities in design or other detail are necessary to ensure perfect synchronism, and would it be reliable?

Best Answer to No. 374 *(awarded* 10*s.)*.—In order to ensure perfect synchronism between the machines, an extra or synchronising connection must be made between the two armature windings. This is best effected by adding a slip-ring to the motor and another to the dynamo, each connected to a coil or commutator segment. An electrical connection between these two slip-rings after the motor has been speeded up will serve to lock the armatures in synchronism. For starting the motor it would be necessary to first cut out the starting resistance, R_1 (Fig. 1), and then

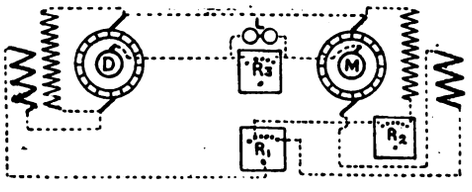

FIG. 1.

adjust the shunt regulating resistance, R_2, until the synchronising lamp or lamps, L, ceased to "beat," showing that the armatures were running at practically the same speed; finally, the resistance, R_3, would be cut out, and the "electrical coupling rod" established between the two armatures.

For the satisfactory working of such an arrangement the following considerations must be borne in mind when designing the machines and afterwards in running them: (1) the pole-faces and armature cores must be of similar type, although not necessarily of the same size; (2) the armatures must be wound to run normally at equal speeds; (3) both machines should have similar characteristic potential curves; (4) if the dynamo speed is likely to vary much, these characteristics should be as straight as possible—*i.e.*, the field magnets should be designed with a low induction or fairly large air-gaps used; (5) the dynamo should be compound-wound to neutralise the "drop" in the machine, and the motor should have a reversed compound winding to prevent the speed tending to fall with increase of load; (6) when the machines are in operation the rheostat, R_3, should occasionally be switched off and R_2 readjusted if found necessary (owing to differences of temperature in fields, etc.).

Unless the above precautions are observed, surgings will take place between the armature windings, with consequent sparking at the brushes, excessive heating, and unnecessary waste of power. An alternator and synchronous motor (with the same number of poles) would be rather preferable to the method just described, but such a combination is apparently not within the scope of the question.—DISPAR.

Answer to No. 374 *(awarded* 5*s.)*.—There are two methods of obtaining this object—one employing continuous and the other alternating currents. For the first method the dynamo and motor would both have to be separately excited from some perfectly constant source, such as a storage battery. The connections between dynamo and motor would be otherwise exactly as usual (see Fig. 1). Any speed variation on the dynamo will

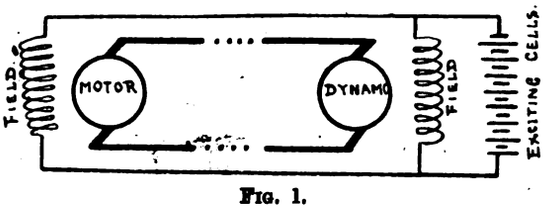

FIG. 1.

produce an exactly proportional variation in its internal armature voltage, and a very nearly proportional variation in its external terminal voltage, with the result that the corresponding motor voltages will also vary very nearly proportionately to the dynamo speed. The motor being separately excited, these voltage changes will cause its speed to very closely, though not quite exactly, follow the dynamo speed. If E and E_1 are the internal (armature) voltages of the dynamos at two speeds, R and R_1 respectively, and e e_1 are the volts lost in the resistances of dynamo armature, motor armature, and line in the two cases (if the torque required from the motor is constant at all speeds, the current will remain constant, and e will equal e_1), then the ratio of the two dynamo speeds, $\frac{R}{R_1}$, will equal $\frac{E}{E_1}$, whilst the ratio of the corresponding motor speeds will eqnal $\frac{E-e}{E_1-e_1}$, and this ratio may be made to differ as little as necessary from $\frac{E}{E_1}$ by making the armature and line resistances low enough (by using machines rather large for the work and a large section for the line wire) and so reducing e and e_1. It may be pointed out that, even if the torque and current are not constant, the effect of changes in armature reaction is negligible, for whilst an increase in current lowers the voltage given out by the dynamo at a given speed, it also weakens the motor field, and so enables the lower dynamo voltage to produce practically the same motor speed as if no armature reaction existed, the two effects nullifying one another.

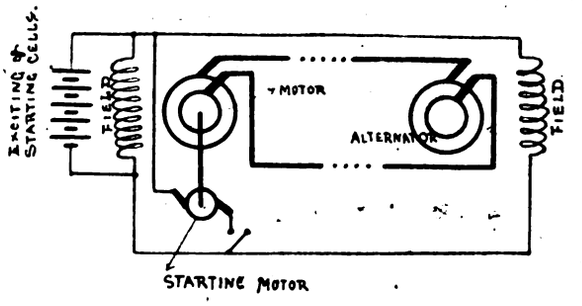

FIG. 2.

The second method, employing alternating currents (Fig. 2), involves the use of a synchronous motor. Such a motor will run at absolutely the same speed as the alternator supplying it, unless a sufficiently sudden change in load or current occur to actually throw it out of step. In the case under consideration it is not of much importance whether a single-phase or a polyphase current be employed. The machines must be separately excited from some continuous-current source, which may also conveniently be used for starting the motor by means of a small auxiliary continuous-current motor connected to the spindle (as

Digitized by Google

shown in Fig. 2). It is, however, quite possible to start a synchronous motor, if of the polyphase type, at light load by means of the alternating current, by leaving the motor field unexcited and passing an alternating current (which may require to be two or three times the full-load current) through its armature. In the present case this self-starting would be especially easy, since the alternator has apparently no other work to do beyond driving the motor, and, therefore, the two machines could be connected together before starting the alternator. In this way the motor would start long before the alternator had attained full speed, and a much smaller starting current would be required. The question of the method of starting has a certain effect on the design, as a motor with large armature reaction and small air-gap would be preferable if the machine is to be self-starting. Beyond this, the only other point to be considered is the flywheel effect of the armatures. The alternator armature should have as *great* a flywheel effect as possible, so as to prevent *sudden* changes in speed, whilst the motor armature should have as *little* flywheel effect as possible, so as to be ready to follow the changes in periodicity sharply. In fact, if the speed variations are at all sudden, it will not be possible to utilise the alternate-current scheme. The permissible amount of sudden speed variation is increased the smaller the number of poles on the motor, so that a very low periodicity (20 to 25 ⁓) should be chosen if not otherwise determined.

To sum up, the alternating-current scheme gives more exact correspondence in speed between dynamo and motor, but it is not quite reliable, especially with sudden speed changes. The continuous-current scheme, on the other hand, is absolutely reliable, but the motor speed is not quite proportional to the dynamo speed.—Q.

Answer to No. 374 (*awarded* 5*s.*).—A series-wound dynamo will drive a series-wound motor (Fig. 1) at a speed corresponding to its own, and whether the load on the motor be large or small, the motor must run at the same speed as the generator, and will vary in speed as it varies. The solution of this problem, to obtain synchronism of the two machines, consists in the proper design of dynamo and motor, so that their characteristic curves fit each other.

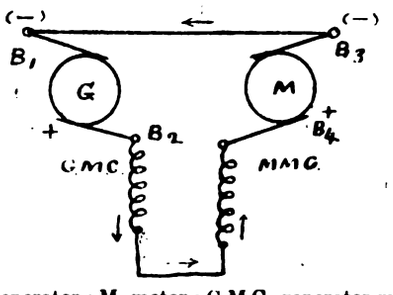

FIG. 1.—G, generator; M, motor; G M C, generator magnet coils; M M C, motor magnet coils; B_1 B_2 B_3 B_4, brushes.

Beyond this no other peculiarity in design or other detail is necessary to ensure constant speed of the motor at all loads, provided the generator be driven at a constant speed and the system becomes perfectly self-regulating. Kapp, in his book on "The Electric Transmission of Energy," shows, by means of a diagram (which I reproduce) how this is accomplished. Let, in Fig. 2, O E represent the ordinary characteristic of a series-wound dynamo, the curve being drawn for a constant speed of, say, 1,000 revolutions per minute. Let O *e* represent the characteristic of the motor also for, say, 1,000 revolutions per minute. The counter E M.F. developed in the armature of the motor at that speed is represented by the ordinates of the curve O *e*. Thus to a current O C will be opposed an E.M.F., C B; to a current O C_1 will be opposed an E.M.F., C_1 B_1, and so on. In the dynamo the E M.F. corresponding to the current O C is C D, and that corresponding to the current O C_1 is C_1 D_1. Draw O R so inclined to the horizontal that the tangent of the angle R O X represents to the scale of the diagram the numerical value of the sum of the resistances $(R+r+s)$ of dynamo, motor, and line, then the E.M.F. lost in overcoming these resistances is for the current O C evidently C A, for the current O C_1, C_1 A_1, and so on. The ordinates between the straight line, O R, and the characteristic curve, O E, represent, therefore, the counter E.M.F., which must be developed in the armature of the motor at various currents. If the current is O C, the counter E.M.F. is A D; if the current is O C_1, the counter E.M.F. is A_1 D_1, and so on. Now, the counter E.M.F. of the motor, if running at a constant speed of 1,000 revolutions per minute, is given by the curve O *e*, and it will be seen that if the ordinates of this curve are for every current equal to the ordinates contained between O R and O E, the motor suits perfectly the requirements of the generator, and it will run at a constant speed. The motor will run at that speed whether the current be O C_1 or O C, provided that C_1 A_1 = B_1 D_1, and C A = B D. Even if the characteristics do not fulfil the condition C A = B D over the entire range, by testing we will generally find two points, C_1 and C, tolerably far apart for which the condition is fulfilled, and between which the deviation of one curve from the form

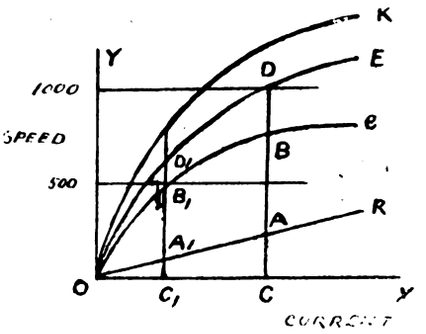

FIG. 2.

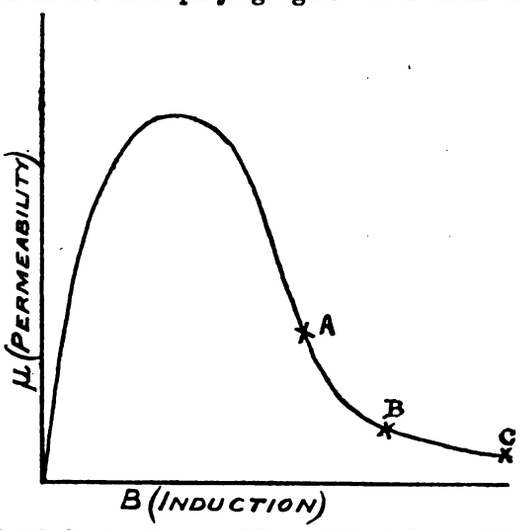
demanded by the other is very trifling. The system will become self-regulating between these limits. If it is necessary to run any two machines which happen to be at hand for constant-current transmission, and the dynamo and motor have not got their characteristics related in a fixed manner, we must make them agree by inserting a resistance in circuit (see Fig. 2). Let O *e* = the characteristic of the motor, and O K = that of the generator. In this case they do not agree, but by putting a resistance in circuit so that O K is brought down to the line O E, then the dynamo and motor will suit the requirements of the case, provided that the conditions already given are fulfilled. As there is some loss of energy by the introduction of the resistance, it is better to make the machines have as near as possible the required characteristics, and so have as little variation as possible in the way of a resistance to introduce. This system is perfectly reliable.—J. A.

Answer to No. 374 (*awarded* 5*s.*).—The requirements stated in this question are rather difficult to satisfy in the case of continuous-current machines. The simplest and most reliable way out of the difficulty would obviously be to employ a polyphase generator which would drive a synchronous polyphase motor; but the question, which specifies a continuous-current set, does not admit of this. A good way to solve a problem of this kind is to determine, first of all, what would be the *ideal* solution, and then, by careful designing, to endeavour to approximate as nearly as possible to it. Now, the ideal method in the present case would be to employ two magneto-electric machines—that is, machines having permanent magnets instead of the customary electromagnets. In this case the speed of the motor would vary directly as the back E M.F. of its armature. This would depend upon the E.M.F. of the dynamo, and the E.M.F. of the dynamo would, in turn, vary directly as its speeds. Thus the speed of the motor would to all intents and purposes correspond to that of the dynamo. The demagnetising effect of the armature current would not, as might be supposed, interfere with this result, for, whilst the demagnetising action of the generator armature would cause the voltage to fall slightly (and consequently tend to lower the speed of the motor), the demagnetising action of the motor's armature would tend to raise the speed of the motor, thus compensating for the lowering of the voltage. This method, however, is impracticable on account of the

Digitized by Google

massive field magnets that would be required—it being impossible to get anything like the flux density in a permanent steel magnet that can be attained in an electro-magnet, and also because such a permanent magnet could not be relied upon to retain its magnetism properly.

The problem that confronts us is this: To design a machine in which, whether running as a dynamo or motor, the strength of the field shall remain practically constant with varying speeds and voltages, as would be the case with a magneto-electric machine. The reason of this will be apparent when we come to consider the working of series and shunt wound machines under the conditions stated in the question. Two series machines would give good results within certain limits, but at light loads (and consequently with lower flux densities in the magnets) the speeds of the two machines would probably not be in very close agreement unless the permeability curves of the iron or steel of the two magnets happened to correspond exactly, and this, unfortunately, cannot be relied upon for low inductions. Therefore, the induction in the magnets must remain fairly high for all voltages and speeds that will be required in practice. For this reason series-wound machines will not be suitable. In shunt-wound machines the induction in the magnets would remain more nearly constant for varying speeds than it would in the case of series-wound machines. And by slightly modifying the proportions of the shunt machine we can obtain practically what is required. Consider for a moment the permeability curve for iron or steel of average quality. The general contour of such a curve is shown in the accompanying figure. It is usual to work



Sketch showing Contour of Permeability in Iron and Steel.

somewhere on the curve between the points A and B. It will be noticed that between the points B and C the permeability remains practically constant with varying inductions. Let the magnet cores be made longer than usual, so as to carry a heavy shunt winding, and work at an induction between the points B and C on the curve. In cast steel this will be when B_{11} is about 135,000, and in cast iron when B_{11} is about 70,000. For the same reason the induction in the armature should also be fairly high. In machines designed on these lines the magnetic induction will remain very nearly constant within wide limits of speed variations; and what variation there is in the magnetic induction will take place simultaneously in both machines, as different samples of iron or steel (by the same maker) differ but very slightly in their magnetic qualities at the higher flux densities. The armatures should be long and of correspondingly small diameter, so that the motor may have a small moment of inertia in order that it may respond quickly to variations in the supply voltage. It goes without saying that the armature resistance should be kept as low as possible, as the loss of volts in the armatures at full load will cause the speed of the motor to fall below that of the generator. A shunt machine embodying the above modifications of design will approximate very nearly to the simple magneto machine; and two such machines will, I believe, satisfactorily fulfil the requirements as stated in the question.

In the above, it is not assumed that, as the two machines are required to be only a *short* distance apart, the drop in the leads will be negligible. Of course, if they were placed any considerable distance apart, the loss of volts in the leads at full load would complicate matters and render the motor less susceptible to variations in the speed of the dynamo.—F. W. D.

LEGAL INTELLIGENCE.

ELECTRICAL ENGINEERING COLLEGE.

The case of G. W. de Tunzelmann came before Mr. Registrar Giffard last Friday. The bankrupt stated that he was proprietor of the Electrical and General Engineering College and Experimental Works at Penywern-road, Earl's Court, from 1893 to 1899, when he sold the business to a limited company then formed to acquire it. The company, which had a nominal capital of £15,000, of which about £1,500 was subscribed, recently went into voluntary liquidation. The bankrupt further stated that in March, 1897, he promoted a company, having a nominal capital of £40,000, of which about £3,500 was subscribed, for the purpose of acquiring from him two patents for electric welding apparatus. He had since acted as director and also as consulting engineer for the company, and attributed his insolvency mainly to losses and expenses incurred in connection with the electric welding company, and by the transfer of the electrical college and works to a company. The examination was concluded, the statement of affairs disclosing an unsecured indebtedness of £9,197, and no available assets.

NATIONAL TELEPHONE COMPANY v. HUTTON.

Test Case.

Mr. A. T. Hutton, veterinary surgeon, Barnstaple, was on Monday sued at Barnstaple County Court by the National Telephone Company for £6. 10s., one year's rent for a telephone. It was a test case. Mr. R. Hendy appeared for plaintiffs, Mr. A. F. Seldon for the defendant. Defendant took the telephone on a yearly tenancy from Dec. 22, 1899. Only one year's rent had been paid, the wire being recently disconnected.

Mr. Drummond, district manager for the company, in cross-examination, said he understood Mr. Hutton considered he ought to have communication with Ilfracombe, Combemartin, Lynton, and elsewhere. He admitted a letter from Mr. Hutton, saying he had not the advantages which it was represented he would have. The establishment of the trunk system rested, he observed, with the Postmaster-General. The company only had the right of user, and in consideration of such trunk line not being established, subscribers were allowed an annual rebate of £1. 10s. Mr. Seldon further cross-examined with a view of showing that there had been several complaints about the trunk line not being established, while some time ago an indignation meeting was held at Barnstaple with regard to the matter.

Mr. Cox, district canvasser, denied the suggestion that he had given promises when obtaining orders a couple of years ago that the trunk system should be established forthwith.

Mr. Seldon declared that he had given such a promise to himself and others, and it was on this misrepresentation that orders had been obtained.

His Honour Judge Beresford said defendant could not get over the agreement, and judgment was for the amount claimed, but without costs.—*Western Morning News.*

CARRALL v. NEW BRITISH INCANDESCENT ELECTRIC LAMP COMPANY.

In the Chancery Division, Mr. Justice Byrne had before him on Wednesday in this debenture holder's action a motion for judgment, which came on in default of appearance by the company. The company was formed in 1898 with a capital of £30,000, and it issued debentures for £7,950, of which the plaintiff was the holder of £2,000. The debentures were a charge on all the property of the company, and the plaintiff's moneys had become payable. It was stated that a distress for rent had been put in, and that an order for the appointment of a receiver had been made by Mr. Justice Buckley.

Mr. Justice Byrne made an order in the common form.—*Financial Times.*

H. G. MASSINGHAM, EXETER.

The first meeting of creditors of Henry George Massingham, of 15, Southernhay West, Exeter, managing director of the West of England Boot and Shoe Supply Company, Limited, and lately carrying on business at 23, Victoria-parade, Torquay, as an electrical engineer, was held on Thursday week at the Castle of Exeter, before the official receiver (Mr. T. Andrew). The debtor's statement of affairs showed gross liabilities to the amount of £7,827. 8s. 10d., which are expected to rank at £2,689. 13s. 4d. His assets amount to £311. 11s. 5d., leaving a deficiency of £2,378. 1s. 11d. The causes of failure alleged by the debtor were losses in connection with electric light undertakings, moneys paid for and liabilities incurred on behalf of the West of England Boot and Shoe Supply Company, Limited. After the production of the

Digitized by Google

official receiver's statement, the public examination was adjourned until June 20.

CHLORIDE ELECTRICAL STORAGE SYNDICATE, LIMITED, v. FITCH.

A consent order was made this week in the Chancery Court by Mr. Justice Cozens-Hardy for an injunction in this action to restrain the use of a secondary battery in an electric launch on the Thames in breach of the Rhodin patents, of which the plaintiff company have the English rights. The kind of battery is known as the "R plate battery." The defendant had bought the storage battery in ignorance of its being an infringement, or that it was not made by the British proprietors. Mr. Stewart Smith was for the plaintiff company, and Mr. Fitch for the defendant.

COMPANIES' MEETINGS AND REPORTS.

CALLENDER'S CABLE AND CONSTRUCTION.

The annual general meeting of the shareholders of this Company was held at Hamilton House, Victoria-embankment, under the presidency of Mr. Henry Drake.

The Chairman moved the adoption of the report (already published in this journal), and in doing so expressed the hope that the balance-sheet would be regarded by the shareholders as satisfactory. The Company had had a very successful year, and the figures showed a very healthy state of things, considering the much larger business done by the Company. The preference share capital had been doubled, and now stood at £200,000. It might appear, perhaps, to some of the shareholders that the amount carried to reserve (£23 616) was large, but, in view of the extensive business which the Company were doing, he thought that they would agree that the directors ought to be careful. It must also be remembered that as time went on competition became very keen, and the tendency was to make prices closer. The prospects of the Company for the present year were excellent.

Major W. M. Mackenzie seconded the motion, which was adopted unanimously.

A resolution for the payment of the usual dividend on the ordinary shares of 10 per cent. and bonus of 5 per cent., making 15 per cent. in all for the year, having been passed, the proceedings closed.

NEW GENERAL TRACTION.

The annual meeting of the proprietors of this Company was held at the Cannon street Hotel on Tuesday.

Captain Francis Pavy, who presided, stated that the directors had not embarked in any doubtful projects, but had confined the Company's operations within a small compass. They had not sought to get the public to join them in working out large and uncertain schemes, nor had they placed the Company in jeopardy by issuing any large amount of capital bearing a high rate of interest—in fact, they had worked more as a limited partnership than anything else. This was the fifth year of the Company's existence, but only last year was any payment made to the directors, and the present was the first time that any distribution had been proposed on the ordinary shares. He thought that this was evidence of a careful and conservative policy. They had very able experts in the business and they had examined numerous schemes which had been submitted to them, but in the past year they only came across one or two that appeared worth following up. On these they had spent both time and money, and they were considering new business now but in taking new business they must have a chance to live. After paying a dividend of 4 per cent. on the ordinary shares, amounting to £4,800, £41.135 remained to be carried forward, and adding to that sum the general reserve and the reserve against goodwill, they had over £90,000 to their credit undivided. This was on the principle of taking at their par value the shares and the securities which were received in payment for work carried out by the Company. They were only interested in a few undertakings—the Douglas tramways, the Norwich tramways, the Coventry tramways, and tramways at Philadelphia—of the prospects of all of which he spoke hopefully. The directors had not wished to issue further 6 per cent. preference shares, and they had themselves found the money that was required for completing works in hand. This accounted for the large item of "loans secured," £157 000. Their undertakings would now be completed within the next few months, and they had come to the conclusion that it would be best to issue immediately £200,000 of 5 per cent. debentures. In conclusion he moved the adoption of the report and accounts.

The Hon. A. G. Brand, M.P., seconded the motion, which was adopted.

CHISLEHURST ELECTRIC SUPPLY.

Directors: A. Travers Hawes; Edmund Charrington; James Ford; Francis E. Gripper. Secretary and manager: F. S. Hanning, Electricity Works, Chislehurst.

In their report for the year ended Dec. 31, 1900, the directors state that the supply of current during the year has been maintained steadily and uniformly, and has given satisfaction to the consumers. The number of new lamps added has not proved as large as was anticipated, the number having risen from 4,017 8 c.p. at the end of 1899 to 4,987 at the end of 1900. There are already signs of better progress in the present year, and several new installations are being completed. Extensions of mains are also in progress in several directions. After paying the debenture interest and meeting the loss on wiring work which was caused owing to the small amount of business done, there remains £102. 2s. 3½d., which the directors propose to carry forward. Debentures to the extent of £5,000 have been issued to Messrs. Edmundsons' Electricity Corporation during the year on account of the amount due to them under their contract work. Mr. Charrington, one of the directors retires by rotation, and, being eligible, offers himself for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Glasgow.—The Corporation invite tenders for the supply of electricity meters. Tenders by June 10. Details in our advertisement columns.

Rochdale.—The Corporation invite tenders for six specimen electric tramcars. Tenders by June 7. Details in our advertisement columns.

Islington.—The Lighting Committee invite tenders for free or assisted wiring. Tenders by June 11. Details in our advertisement columns.

Glasgow.—The Corporation invite tenders for the supply of branch rubber covered cables. Tenders by June 7. Details in advertisement columns.

Edinburgh.—The Corporation invite tenders for ash-conveying plant, Dewar place station. Tenders by June 15. Details in our advertisement columns.

Dundee.—The Town Council invite tenders for the overhead equipment of Seagate route. Tenders by June 5. Details in our advertisement columns.

Hendon.—The Urban District Council invite tenders for the wiring of the new Council offices. Tenders by June 5. Details in our advertisement columns.

Worksop.—The Urban District Council invite tenders for the supply of 150 electricity meters. Tenders by May 29. Details in our advertisement columns.

Salford.—The Corporation invite tenders for the supply and delivery of additional steel poles, cast-iron bases, etc. (Contract No. 16), in connection with the electric tramways. Tenders by June 3. Details in our advertisement columns.

Uxbridge.—The Uxbridge and District Electric Supply Company invite tenders for erection of a generating station on land adjoining the Waterloo-road. Specifications, etc., can be obtained from the Secretary's Office, 1, Vine-street. Tenders by June 4.

Digitized by Google

Sunderland.—The Corporation invite tenders for the supply of steel plate coal bunkers and overhead gantry. Tenders by May 31. Details in our advertisement columns.

West Stanley (Durham).—Tenders for electric lighting are invited on inspection for new Catholic church, West Stanley. Apply to Rev. J. Thompson. Tenders by June 1

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection of dry-back marine-type boilers. Tenders by June 8. Details in our advertisement columns.

Farnworth.—The Urban District Council invite tenders for the overhead equipment of about five miles of tramways and tramway poles. Tenders by June 7. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of special (permanent way) track work cross-over tracks, etc. Tenders by May 25. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of electrical fittings for the lighting of their Queen's-road car-shed. Tenders by June 4. Details in our advertisement columns.

London, E.C.—The East Indian Railway Company invite tenders for electric overhead travelling cranes, etc. Specification may be seen at the Company's Offices, Nicholas-lane, London, E.C. Tenders by June 12.

Dublin.—The Lighting Committee invite tenders for the supply and erection of motors and motor-generators, accumulators, meters, and works wiring. Tenders by June 3. Details in our advertisement columns.

Islington.—The Lighting Committee invite tenders for the painting of the arc lamp columns and crutches of which 398 are in use in the borough. Tenders by June 11. Details in our advertisement columns.

Dublin.—The Lighting Committee invite tenders for the supply and erection of main switchboards, sub-station switchboards, transformers, arc lamps, and arc lamp pillars. Tenders by June 3. Details in our advertisement columns.

Exeter.—The Town Council invite tenders for erection of the buildings of their new electricity generating station. Specifications, etc., may be obtained from Mr. Donald Cameron, city engineer and surveyor. Tenders by June 14.

Salisbury.—The Urban Sanitary Authority invite tenders for erection of a chimney shaft, 120ft. high and 5ft. internal diameter. Specifications, etc., may be obtained from Mr. Alfred C. Bothams, A.M.I.C.E., Municipal Offices, Salisbury. Tenders by May 25.

Aldershot.—The Urban District Council invite tenders for erection of buildings and shaft in connection with their electric lighting station. Specifications, etc., may be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., surveyor. Tenders by June 4.

Edinburgh.—The Corporation invite tenders for the electric lighting installation, etc., of the first portion of the Colinton Mains Fever Hospital, the number of lighting points being about 1,550. Tenders by June 12. Details in our advertisement columns.

Exeter.—The Council invite tenders for boiler-house equipment, pipes, etc., engine-room equipment, switchboards, connecting cables, coal bunkers and conveyors, and feed and condensing water tanks. Tenders by June 14. Details in our advertisement columns.

Dundee.—The Gas Commissioners invite tenders for steel steam piping, valves, and accessories, at the electric lighting station, Dudhope crescent-road. Specification, etc., may be obtained from Mr. Walter H. Tibbenson, city electrical engineer, Dudhope-crescent-road. Tenders by May 30.

Doncaster.—The Corporation invite tenders for steel grooved girder tramway rails for eight miles of tramways in the borough of Doncaster and adjoining neighbourhood. Particulars may be obtained at the office of the borough surveyor, Mr. W. H. R. Crabtree, M.I.C.E., 3, Priory-place, Doncaster. Tenders by June 3.

Taunton.—The Corporation invite tenders for the construction, supply, and erection of one 250-kw. steam alternator, one 15-kw. motor generator, switchboard extensions, one water-tube boiler, superheater, jet condenser, and air-pump, and sundry pipe extensions. Tenders by June 11. Details in our advertisement columns.

Burnley.—The Electricity Committee invite tenders for (A) five injectors, capable of dealing with 700 gallons per hour; (B) one feed pump, capable of dealing with 3,500 gallons per hour. Specifications, etc., may be obtained on application to Mr. Robt. Birkett, the borough electrical engineer, Aqueduct-street, Burnley. Tenders by June 10.

Madrid.—Tenders are invited by the Spanish Postal and Telegraph Department for the supply of 30,000 zinc cylinders for the service of the Government telegraph stations. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by June 1.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

London, S.W.—Tenders are invited for the supply of 13,400 tons of steel rails and 958 tons of fishplates for the Queensland Railways. Tenders will be received at the Queensland Government Office, 1, Victoria-street, London, S.W., until 2 p.m. on June 11, endorsed "Tender for Steel Rails and Fishplates," and accompanied by a preliminary deposit of 1 per cent. on the tender. Specifications, drawings, etc., may be obtained at the office of the Agent-General for Queensland.

Uganda.—The Crown Agents for the Colonies, acting on behalf of the Uganda Railway Committee, invite tenders for the supply of galvanised iron wire, specification and form of tender for which can be obtained on application to the Crown Agents, at whose office the drawing will be on view between the hours of 10 a.m. and 4 p.m. (Saturday, 10 to 2). Tenders to be delivered, addressed to the Crown Agents for the Colonies, Downing-street, S.W., and endorsed "Tender for Galvanised Iron Wire, Uganda Railway," not later than noon on June 11.

RESULTS OF TENDERS.

Burnley.—The Electricity Committee have accepted the tender of the Oldham Boiler Works Company, Limited, for two Lancashire boilers, 28ft. by 7ft., with fittings, at £700.

Wrexham.—The Town Council have accepted the tender of Whitaker Bros., Limited, Dudley and Wrexham, for supplying and fixing electric calls for the fire brigade, at £62. 10s.

Battersea.—The Electricity Committee recommend that four additional telescopic ladders for use in connection with electric arc lamps be procured of Heathman and Co., at £29. 2s. each.

Woolwich.—The Electricity Committee have accepted the tender of Smith and Sons, South Norwood, at £40 574, for the erection of buildings in connection with electricity works and dust destructor.

Cardiff.—The following tenders have been accepted: J. Williams and Co., Cardiff, refuge pillars; J. Preece, Bristol, brackets; Thornton and Co. and Bergheil and Young, feeder and section pillars; Bock and Marsh and F. Smith, trolley, span, and guard wires; R. W. Blackwell and Co. insulators and line suspensions.

Barrow-in-Furness.—The Corporation have accepted the following tenders: British Insulated Wire Company, Limited, Prescot, paper-insulated lead-covered concentric cables, at £2,742 (approximate); Doulton and Co., earthenware conduits and pipes, at £592 (approximate) and Albion Clay Company, Limited, London, at £178 (approximate); Mavor and Coulson, Limited, Glasgow, balancing transformer and switchboards, at £583 (approximate).

Kingston (Surrey).—The following tenders have been received for the erection of a chimney shaft at the electric works:

F. and F. H. Higgs	£2,900
R. H. B. Neal	2,430
D. Gibb and Co.	2,400
W. Neil and Co.	2,400
H. Windsor and Co.	2,250
Myles and Warner	2,194
Foster Bros.	2,174
J. Pollard	2,076
F. and E. Davey (accepted)	1,989
Alphons Custodis Chimney Construction Company	1,700

BUSINESS NOTES.

TRACTION.

Hindley.—The question of the purchase of the tramways is still under the consideration of the District Council.

New York.—The tramway strike at Albany, referred to in our last issue, has resulted in the company agreeing to the proposals of the strikers.

Private Bills.—In the House of Commons the Tottenham and Hampstead Junction Railway and the Bexley Tramways Bills have been read a third time.

Blackpool.—The new line of electric tramways to Marton is now in working order, and a public service of cars will be put on the road for Whitsuntide.

London United Tramways Bill.—The Hammersmith Borough Council and the Hampton District Council have both sealed petitions against this Bill.

Surrey.—The County Council have approved the form of their agreement with the London United Tramways Company, and the necessary steps are being taken to carry it out.

Helston.—The Rural District Council have given their consent to the application of the Lizard Light Railway Company to work their proposed line to the Lizard by electricity.

Ramsgate.—The electric tramcar service is now reported to be running with improved smoothness and punctuality, and with a happy immunity from the mishaps which caused some local excitement during the opening days.

Moss Side.—The agreement between the Urban District Council and the Manchester Corporation in regard to the construction of tramways in Moss Side has been completed, and the Corporation have promised to begin the work as soon as possible.

Birmingham.—Success is attending the running of the Bristol-road overhead tramway. On Saturday last £109 odd was taken in fares, and this was repeated on Sunday, when the cars travelled for the first time over the Selly Oak extension of the route.

Scarborough.—The Tramways Sub-Committee have resolved to recommend the Council to apply to Parliament for a Bill empowering them to construct electric tramways within the borough, and failing that, to apply for a provisional order to the same end.

Digitized by Google

Blackburn.—A heavy loss is reported on the working of the Corporation tramways during the past year, this being attributed to the universal adoption of 1d. fares. The result is an increase of fares by ½d. on most of the sections, and the adoption of 1d. stages is recommended.

Devonport.—Although the whole of the track of the Devonport and District Tramways is practically completed, there are some finishing touches to be carried out, and it is certain that the system cannot be opened for public traffic in time for the Whitsuntide holidays.

Bolton.—The monthly report on the Corporation tramways for April shows receipts £6,440, as against £5,638 the previous month; total mileage, 139,233, as against 146,771; passengers carried, 1,279,969, as against 1,350,730; and receipts per car mile, 11·10, as against 9·20 the previous month.

Barnsley.—The provisional order granted by the Light Railway Commissioners for extensions of the Barnsley and district light railway came up for confirmation at the Board of Trade on Wednesday. There was no objection to the preamble, and the adjustment of clauses was proceeded with.

Middlesex.—In addition to the 15 miles of tramways which they have received permission to construct, the County Council now propose to build lines from Wood Green to Finsbury Park, from Waltham Cross to Finchley and Kilburn, from Acton to Willesden and Hounslow, and several others.

West Cumberland Tramways Bill.—All opposition to this Bill, with the exception of that of the Cleator Moor Urban District Council, has been disposed of, and the Light Railway Bill has been dropped. The tramways proposed are from Cleator Moor, through Whitehaven, Workington, Maryport, Allonby, and ending at Silloth.

Brighton.—The question of granting facilities to the Brighton and Rottingdean Seashore Electric Tramway Company and to Volk's Railway to join the two lines by way of Madeira-road was further discussed at the last Town Council meeting, and the Council resolved to adhere to their original decision in favour of the scheme.

Plymouth.—The question of applying in the next session of Parliament for powers to construct a double line of tramways from the existing lines at Mutley through Alexandra-road to Lipson Vale is being considered by the Tramways Committee. It is estimated that the capital cost of the proposed extension will be about £10,000.

The Manchester-Liverpool Monorail.—The Committee of the House of Lords presided over by Viscount Falkland have passed the Bill authorising the construction of the electric express railway between Liverpool and Manchester, subject to the insertion of a clause to the effect that the centre of gravity shall be below the top of the uppermost rail.

Halifax.—The Tramways Committee have decided to reward tram drivers who show themselves especially efficient by paying them an extra 1s. per week wages. Those who remain five years and upwards in the service of the Corporation are to receive similar recognition. The maximum wage thus far paid to tram drivers in Halifax has been 30s. per week.

Worcester.—The report of the directors of the Worcester Tramways, Limited, for 1900 states that the Worcester and district light railways order has been confirmed by the Board of Trade. The Worcester Tramways Bill has been remodelled, and is now unopposed. The Worcester (extension) light railways order is awaiting the confirmation of the Board of Trade.

Aberdeen.—The Town Council have decided to proceed with the reconstruction as a double line of the tramway in Great Western-road between Forbesfield-road and Ashley-road, and also between Great Western-place and Holburn-street; that the line shall be electrically equipped, and the work carried out by the British Insulated Wire Company at the scheduled prices for the present contract.

Leicester.—The report of Mr. E. Manville on the scheme of tramways for Leicester—the first portion of which is given elsewhere—was presented to the Council by the committee on Tuesday last. A difference of opinion occurred, but after considerable discussion—with the exception of the site of the power station—the report of the committee was adopted. Mr. Manville was appointed consulting engineer for the work.

Tyneside Tramways Bill.—In the House of Commons this Bill has been brought up from the Lords and referred to the Examiner of Standing Order proofs. The object of the Bill is to authorise the construction of tramways and a tramroad in the urban districts of Walker, Wallsend, Willington Quay, and Gosforth in the borough of Tynemouth, and in the parishes of Willington and Longbenton in the county of Northumberland.

Glasgow.—The Town Council have resolved: "That it be an instruction to the Tramways Committee to consider the question of possible demands on the police in the event of accidents to overhead wires on tramway routes, and the equipment of the police for the same, and to report." It was pointed out that equipments in the shape of indiarubber gloves and so forth had been provided in Liverpool, Huddersfield, and other places.

Wolverhampton.—After several delays the Corporation have now commenced the work of laying down their new scheme of tramways for the borough. The first section of the line to be dealt with will run from Tettenhall to Queen-square, *vid* Newhampton-road, and on Monday the chairman of the Tramways Committee, in the presence of a number of members of the Corporation, performed the ceremony of "breaking the ground."

Finchley.—Councillor Todd has been appointed chairman of the Tramways and Electric Lighting Committee of the Urban District Council. At the last meeting of the Council a letter was received from the North Finchley Tradesmen's Association urging the Council to secure the insertion of several clauses in the Finchley and Hendon Tramways Bill, the last of which is that "all telephone wires crossing trolley wires be effectively guarded."

Bradford Corporation Bill.—When this Bill came before the Select Committee of the House of Commons presided over by Mr. Heywood Johnstone on Monday, it was intimated that the opposition of the Shipley District Council was withdrawn to the tramway part of the Bill, it having been agreed to strike out Clause 11, relating to the leasing of tramlines. The Committee then proceeded to adjust clauses, and the Bill will be reported for third reading.

Liverpool.—The tramway receipts from both electric cars and horse vehicles for the fortnight ended May 11 amounted to £17,813. 13s., an increase of £3,204. 15s. 7d. for the same period last year. The miles covered number 402,596, an increase of 78 859. The number of passengers carried was 3,858,523, which showed an increase of 1,041,117 over the same fortnight last year. There are now 287 electric cars in use, and only seven horse vehicles remain on the road.

Gateshead Tramways Bill.—Lord Morley's Committee of the House of Lords which deals with unopposed Bills, had before it on Monday the Gateshead and District Tramways Bill, under which authority is given to raise £80,000 of additional capital with which to complete the system of tramways in Gateshead and district, and which received the sanction of Parliament a year or two since. The measure passed the committee, and will be reported without amendment to the House.

Cardiff.—A conference between several members of the Tramways Committee and representatives of the tramway company has been held on the question of the tramways. The proceedings, which were conducted *in camera*, are said to have been of an exceedingly friendly character, and there is every probability of an arrangement being arrived at if Mr. John Glenn, the engineer to the company, and the borough engineer, Mr. W. Harpur, can come to terms as to the value of the existing lines.

Paisley.—It is anticipated that the Glasgow Corporation will accept the running powers over Paisley and district tramways granted by Lord Camperdown's commission. It appears that a representative of the Corporation attended recently at the office of the Secretary for Scotland in Edinburgh when the clause was being adjusted giving Glasgow these running powers. In the event of that arrangement being carried out, Mr. Murphy has undertaken not to ask for running powers into Glasgow.

Canada's Electric Railways.—According to the latest official statistics issued, during the year ended Dec. 31, 1899, the 612 miles of electric railway track in the Dominion of Canada were so used that the total number of miles run by cars was 20,646,847. The number of passengers carried was 104,033,659. Compared with the previous year, the number of passengers carried increased nearly 9,500,000, and the number of miles run by over a million. The amount of paid-up capital invested in electric railways in Canada is over £4,340,000.

The Proposed Solent Tunnel.—We note that it is proposed to commence operations in September next in connection with the scheme to connect the Isle of Wight with the mainland by means of an electric railway under the Solent. The total length of the new line will be eight miles, but that of the tunnel proper will be no more than 2¼ miles. Of the estimated cost of £550,000, as much as £400,000 will be spent on boring under the Solent. When the project is completed, it is expected to make the journey from London to the Isle of Wight in the record time of 2½ hours.

Sheffield.—The Tramways Committee met on Wednesday to make enquiries regarding the difficulty that occurred the other day owing to the men's threat to strike at a moment's notice. A full enquiry was made into the proceedings of the men the night previous to the strike and on the day when the traffic was disorganised. A number of the men who are supposed to have been the ringleaders were brought before the committee to give an explanation of their conduct. The committee did not arrive at any decision, but we understand that some recommendations will be made to the Council at the next meeting on the subject.

Tube Vibration Claim.—Mr Watney sat at the Surveyors' Institution last week as sole arbitrator to consider a claim of £700 made by the vicar and churchwardens of Christ Church, New Bridge-street, against the Central London Railway for damage to the vicarage alleged to have been caused by the construction of the tube railway. The railway company declined to admit any liability for the damage done to the vicarage. Even supposing the cracks were due to the construction of the tube, the claim, it was submitted, was exorbitant, for the whole damage could be repaired for an amount not exceeding £35. The arbitrator reserved his award.

Wakefield.—The tramway syndicate are already taking steps with a view to extending the existing lines, feeling confident, it is said, that their application for a provisional order will be granted. Immediate application is to be made to the Light Railway Commissioners for sanction to the construction of branch lines connecting Lofthouse with Rothwell and so with Leeds, and also Horbury and Ossett with Bradford. Colonel von Donop, of the Board of Trade, has visited Wakefield for the purpose of officially inspecting the Kirkgate Bridge, which the opponents of the tramways scheme allege cannot be used for tramway traffic in its existing form.

Digitized by Google

Newcastle.—The iron posts to carry the electric trolley wires in connection with the new tramways have now been erected on the North-road between the police station and the Blue House, and work is progressing favourably. The City Council have determined, in conjunction with the Walker Council, to oppose the Tyneside Tramways Bill in the House of Commons, in view of the alleged unsatisfactory nature of the decision of the Lords' Committee which found the preamble proved, subject to the undertaking that the promoters would come to Parliament next year to proceed, either by Bill or provisional order, to do in Walker whatever the Corporation of Newcastle had promised to do.

North Lancashire.—According to the local Press, efforts are being made by the large Midland syndicate to buy up the tramways in North Lancashire. The Lancashire and District Tramway Company have had an offer for their Morecambe line, and overtures have also been made for rights to construct electric tramways in the borough of Lancaster, where the Corporation have received sanction for a £70,000 scheme. The syndicate's offer to take over the Corporation's powers has been considered by the Tramways Committee, but it is concluded from what transpired at the meeting that it is very improbable that the Corporation, having made several attempts to municipalise their tramways, will now sell their rights.

Sunderland.—A foot passenger fell in front of an electric car on Saturday, and getting underneath the guard was pushed along some distance. His injuries were serious, his collar-bone being fractured, and several ribs broken, but he is expected to recover. Another extension of the Corporation electric tramways running between the terminus at Roker and Seaside-lane, was approved on Wednesday by Lieut.-Colonel von Donop, of the Board of Trade, and was thrown open to the public the same day. The new line runs along the coast in a northern direction for three-quarters of a mile. The Tramways Sub-Committee have decided to recommend the Corporation not to grant running powers over the borough lines to the British Electric Traction Company, who are about to lay lines between Houghton-le-Spring and other places and Sunderland. They are, however, prepared, we understand, to negotiate with the Electric Traction Company as to through rates for both parcels and passengers.

Clacton.—At a special meeting of the Urban District Council a letter was read from the British Electric Traction Company in reference to their proposal to obtain powers to construct tramways in the town and district. The lines the company would suggest would commence in Great Clacton and run down Pier-avenue to the front. Thence one line would run in a westerly direction to the goods jetty, and another to the north-east along the Parade and Clacton Cliff to Frinton and Walton-on-Naze. The system proposed is the electric overhead trolley. The letter also referred to the electric lighting order the Council have obtained, stating that the company would be prepared to discuss terms, either for the acquisition of such order and carrying out the same, or the taking of the power required for tramways from the Council should they desire to carry out the order themselves. The letter, together with the question of the electric lighting order, was referred to the Council in committee for consideration.

Yarmouth.—At the last Town Council's meeting the Tramways Committee recommended the Council to invite tenders for 14 double-decked cars, the estimated cost of each being £530. It was pointed out, however, that until the Council had decided whether it would work the trams or lease them it was futile to take this course. The matter was then referred back to the committee. The Board of Trade have approved the plans and drawings of the proposed method of construction. In reference to the Gorleston tramways, a letter was read from the British Electric Traction Company, who have become the proprietors of the undertaking, stating that they were desirous of carrying into effect the Yarmouth and Gorleston tramways provisional order of 1897, authorising the equipment of the line for electric traction, which they were empowered to effect with the consent of the Corporation, and which consent they then applied for, and also enquiring upon what terms the Corporation would be willing to supply the necessary energy.

Reading.—The Corporation having failed to come to an amicable settlement with the tramways company as to the price to be paid by the Corporation for the undertaking, Sir Frederick Bramwell, the referee appointed by the Board of Trade, has opened an enquiry into the matter. At the last meeting of the Town Council, Messrs. J. Bowen and I. E. Winslow, the engineers to the Corporation's scheme, reported as to an interview with Colonel von Donop, of the Board of Trade with regard to the proposed doubling of portions of the projected tramways, etc. The question of commencing the construction of the extensions authorised by the provisional order was entered upon, the position in which the Corporation stood being explained, together with the absolute importance of constructing the permanent way and electrical bonding under one contract. Colonel von Donop stated that, all things considered, perhaps the best way out of the difficulty would be to apply to the Board of Trade for a further extension of time. The engineers further state in this report that instead of proceeding with the drawings and specification for the extensions of 1899 only, they are dealing with the whole of the work, and in the course of two or three weeks they will be ready to be laid before the committee for the purpose of advertisement, and that they are convinced that this procedure will prove the more economical plan. The report was adopted, and a memorial to the Board of Trade for a further extension of time was approved.

London Underground Railways.—The Parliamentary Committee on London Underground Railways met again on Tuesday, but before proceeding to take further evidence the chairman (Lord Windsor) expressed on behalf of the committee their very deep regret at the sudden death of Sir Courtenay Boyle. The case of the North-East London Railway was then enquired into. Mr. Jenkin, C.E., stated that in the system proposed no part of the electric circuit was connected with the other. The whole circuit was insulated, and even if the insulation were to break down at one part of the system no danger could possibly occur. It was proposed to have on the North-East London line multiple motors along the train, which would obviate the necessity of a loop at the end of the system and save shunting. There would be ample time for a 2½-minute service. Mr. J. F. Gooday, general manager of the Great Eastern Railway, was examined in opposition to the scheme. The Great Eastern were providing for early morning service trains to carry 850 workmen by increasing the seating capacity of the carriages. They were not prepared immediately to carry out or to go to Parliament with a scheme, but submitted it to the committee in order to show that the question was being considered, and to ask the committee not to pass any scheme that would interfere with their use of the ground under their line. In view of the probable report of the Vibration Committee and the fact that the Central London Railway was not on the right lines, and the proposed North East London Company were not prepared to say what scheme they would adopt, the Great Eastern directors were not ready to recommend their shareholders to find the money for any particular scheme in this Parliament. It was recognised that increased accommodation was required, and the Great Eastern, having practically created the district, ought to provide for it. The scheme which had been considered by the directors, but not formally adopted, was for a line from Chapel End by Low Leyton, under the existing line up to Liverpool street, and then curved round so as to serve the Ilford district and Forest Gate. They would thus duplicate a great deal of their existing suburban lines by the proposed electric underground railway. The committee adjourned until to-day (Friday).

Leeds.—The accounts of the city tramways for the year ended March 25 last show a gross profit of £61,797, and after payment of interest (£16 662) and sinking fund charges (£14,076) there is a surplus of £31,058, as compared with a surplus in the previous year of £6,167. 8s. 6d. The running expenses include £7,038 for depreciation of rolling stock, and in addition to that sum, which has been written off, the Tramway Committee have decided to reserve out of the surplus a further sum of £10,000 to cover the loss sustained by the sale of two old engines at the generating station, which had been replaced by larger units. The surplus, therefore, is reduced to £21,058. 2s. 6d. During the year there has been a great extension in the electric car service, with corresponding advantage to the public and a largely increased income. The receipts from electric traction amount to £133,449, or more than double the income from that source last year, which was £63,436. Horse and steam cars are now being rapidly replaced by electric cars and as was to be expected, the receipts from both those classes of cars are far less than they were 12 months ago. The difference between the receipts and the running expenses for electric traction was £80,834. The total receipts are £183,199, as compared with £129,137 a year ago, an increase of £54,061. The expenditure has increased from £99,110 12 months ago to £121,402, and the sinking-fund charges from £11,809 to £14,075. With regard to car accommodation, the report states that to meet the increased traffic they are at present working the full stock of 130 electric cars. Twenty additional cars will be licensed this week, in readiness for the Whitsuntide holidays; and of the undelivered cars still on order 20 may be expected next month and the remaining 20 during the month of July. The power station is now sufficiently equipped to handle up to 180 cars, with the necessary stand-by of reserve power. The electrical equipment of the Cardigan-road and Victoria-road sections will be completed in about six weeks, and 10 or 12 cars will be needed for this service. Pending the electrical equipment of the Wortley, Armley, and Stanningley sections, now commencing, the management will during this summer have at disposal an ample supply of cars for an increased service to Roundhay. It is therefore decided that the Roundhay Park fare shall be reduced from 3d. to 2d.

London County Council Tramways. — On Tuesday the Highways Committee of the London County Council presented a report on the proposed reconstruction for electrical traction of a further portion of the Council's tramways. The Council has already determined to reconstruct the tramways, rather more than eight miles in length, between Westminster and Tooting, Kennington and Blackfriars, and St. George's-circus and Waterloo-road, and the committee recommended that the tramways to be next dealt with should be those between (1) the junction of Kennington-road with Westminster Bridge-road and St. George's-circus; (2) the Elephant and Castle, and along the New and Old Kent roads, New Cross-road, and Greenwich-road to the terminus at Trafalgar-road, Greenwich; and (3) the Elephant and Castle, *vid* Newington-causeway, to St. George's Church, Borough, and thence *vid* Dover-street to the junction of the New and Old Kent roads. The total length of these tramways is 6 miles 1,317 yards of double (or 13 miles 874 yards of single) track, which is rather less than the length of the Tooting and other lines, in connection therewith, above specified; but the committee were informed that the amount of the traffic per mile on both sections is about the same. The committee have consulted the chief engineer with regard to the steps to be taken with a view to the reconstruction of these other sections of lines being carried out without any unnecessary delay, and, upon his advice, they suggested that, in order that full advantage might be taken of the experience of the various firms of contractors who execute such work, the specifications on which

Digitized by Google

tenders were to be invited should be drawn up in such a manner as to allow the parties tendering to include their own details of conduit construction. The interests of the Council would be fully safeguarded by the general conditions which were usually attached to the Council's contracts and the issue of a detailed specification with quantities of the track rails the conductors, and the road-work; but instead of a particular design of yoke and insulator being specified and tenders according to that design only being asked for, parties tendering would be at liberty, if the Council adopted the committee's suggestion, to submit their own designs. The committee were informed that this practice was usual with regard to other kinds of work; indeed, it was adopted by the Council with regard to the tenders recently invited for the supply of the boilers and stokers required for the electricity generating station to be erected at the Camberwell tramways depôt, in which instance working drawings were not issued, but the results desired were clearly specified, and the parties who tendered submitted their own details. Of course, whatever system of electrical traction the Council might eventually decide to adopt for the two sections of its tramways specified above, would, under the London County Tramways Electrical (Powers) Act, 1900, require the approval of the Board of Trade, and the road authorities concerned are entitled to be heard by the Board thereon. The following recommendation was approved: "That the Highways Committee be authorised to prepare specifications and to invite tenders by public advertisement for the reconstruction for electrical traction of those portions of the Council's tramways between (*a*) the junction of Kennington-road with Westminster Bridge-road and St. George's circus; (*b*) the Elephant and Castle, along New and Old Kent roads, New Cross-road, and Greenwich-road, to the terminus at Trafalgar-road, Greenwich; and (*c*) the Elephant and Castle, *vid* Newington-causeway to St. George's Church, Borough, and thence *vid* Dover-street to the junction of New and Old Kent roads; and that the parties tendering be allowed to submit their own designs of the yoke and insulator which they propose to supply." The Select Committee of the House of Commons presided over by Mr. Seale Hayne has decided that the preamble of the London County Council Tramways Bill is proved, but rejected tramway No. 6 (the extension along the Farringdon-road) and the portion of No. 16 between Westminster Bridge road and Waterloo road—that is, the York-road portion of the Westminster and Borough High-street tramway.

LIGHTING AND GENERAL.

Whitehaven.—The Town Council propose to raise the price of current.

Share Market.—Electric shares have kept pretty steady during the week.

Southend.—The Corporation have received sanction to raise a loan for the electric lighting of the town.

Berwick.—Messrs. Edmundsons, Limited, are negotiating for the purchase of the old shipyard for an electric lighting station.

Hornsey.—The Council have received sanction for the inclusion of Clerkenwell Detached in the area to be lighted by electricity.

Gillingham.—The District Council have decided to purchase the undertaking of the electric light works in accordance with the recent agreement.

Haywards Heath.—The Urban District Council are asking the Postmaster General when they might expect telephonic facilities at Haywards Heath.

Quarry Bank.—Messrs. Sidaway, Dunn, Shaw, Tandy, Goodwin, and Turner have been appointed a committee to investigate the question of public lighting.

Swansea.—A committee has been appointed by the County Council to report on the advisability of procuring a license for the municipalisation of telephones.

Rattray.—We understand that at a recent private meeting the Provost broached the subject of the electric lighting of the burgh, but nothing definite was arrived at.

Electric Lighting Orders.—Electric lighting orders have been granted by the Board of Trade to Beverley, Honley, Ripon, Todmorden, Workington, Birstall, and Skipton.

Great Harwood and Rishton.—The District Council consider the charge of 7d. per unit inserted in the Rishton, Great Harwood, and Clayton le Moors electric lighting scheme is much too high.

Western Telegraph Co.—The directors have declared an interim dividend of 3s. per share or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended March 31, payable on June 24.

Bury St. Edmund's.—Mr. L. Paton Greig has been appointed borough electrical engineer in succession to the late Mr. Roe, Mr. Greig having acted as chief assistant since and before the works were started.

Hastings.—Three electric arc lamps are to be erected in Norman-road, in substitution for the gas lamps, at £34. 10s. per lamp. The estimated annual cost of maintaining the lamps is £14. 8s. 2d. per lamp.

Hackney.—The Borough Council are prepared to supply electricity to the Stoke Newington Borough Council on the east side of High-street, Stoke Newington, provided all necessary powers and consents can be obtained.

Cricket.—The annual match, staff *v.* works of Glovers, Limited, was played on the 18th inst. at Trafford Park, and resulted in a victory for the works by 52 runs to 17. A. Horton took seven wickets for two runs for the winners.

Beverley.—The Town Council have asked Messrs. Gibbings and Baker to report what portion of the works should be proceeded with forthwith, and generally as to the best method of carrying out the works authorised by the order.

Kensington.—Electric arc lamps are to be used for lighting the principal thoroughfares in the borough—viz., Kensington High-street, Kensington-road, Brompton road, Holland Park-avenue, and High-street, Notting Hill. The cost of the installation will be £3,900.

Alloa.—Mr. Hogarth (of Messrs. Buchan and Hogarth, electrical engineers, Edinburgh) has reported on the various contracts and tenders in connection with the electric lighting scheme now in course of promotion by the Town Council. He estimates the cost at £8,500

London Gazette.—The estate of W. Haines, 261, Bury New-road, Whitefield, Lancashire, has been released from trusteeship.—A final meeting of the United Telephone Company, Limited (in liquidation) is announced to be held at 5, Moorgate-street, E.C., on June 26 at 2 p.m.

West India and Panama Telegraph Co.—The accounts for the six months ended Dec. 31 last show a credit balance of £3,337, to which has to be added £2,379, being interest on investments and £955 brought forward, making a total of £6 670, which it is proposed to carry forward.

Dumfries.—The Electric Light Committee of the Town Council, in view of the difficulties disclosed by Mr. Ritchie's report, have resolved to recommend the Council not to entertain the idea of a water installation, and an engineer is to be appointed to carry through a steam installation.

Southwark.—The City of London Electric Lighting Company, Limited, have notified their intention to apply to the Board of Trade for a provisional order to empower them to supply electric energy for all purposes throughout the whole area of the metropolitan borough of Southwark.

Guildford.—We understand that there will be no difficulty between the Council and the Guildford Electricity Supply Company with regard to their application to lay mains in certain of the roads in which paving works are proposed to be carried out before such works are commenced.

Cable Communications.—At Wednesday's meeting of the Cable Communications Committee at St. Stephen's House there were present Lord Balfour (chairman), the Marquis of Londonderry, the Earl of Hardwicke, the Earl of Onslow, Major-General Sir J. C. Ardagh, Rear-Admiral R. N. Custance, and Mr. J. H. Lindsay (assistant secretary). Mr. Robert Kaye Gray, of the India Rubber Gutta Percha, and Telegraph Works Company, gave evidence.

London County Council.—The London County Council on Tuesday decided to ask the Board of Trade to promote a Bill providing for the inspection of the lists of share and debenture holders in companies supplying gas, electricity, water, or hydraulic power, or owning docks or wharves, or undertaking tramway, telephone, or other public services in London, an aggressive move to which the investors in these companies will find it easy to reply, apart from the fact that the Government will probably not take the slightest notice of it. The Council have decided to increase the rate of wages for wiremen in the Council's list from 8½d. to 9½d. per hour, and also to lend the Hampstead Borough Council £17,225 for electric lighting purposes.

Stock Exchange.—The Stock Exchange Committee have appointed May 30 special settling day for the General Electric Company (1900), Limited, 18,000 5 per cent. cumulative preference shares of £10 each, fully paid, Nos. 7,001 to 25,000, and £150,000 4 per cent first mortgage debenture stock, and have also ordered the said securities to be quoted in the official list. The committee have been asked to appoint a special settling day in the British Electric Traction Company's further issue of 30,000 6 per cent. cumulative preference shares of £10 each, £6 paid, Nos. 160,001 to 190,000; and the West London and Provincial Electric Supply Company's 9 391 ordinary shares of £1 each, fully paid, Nos. 7 501 to 11,425, 12 926 to 15,025, and 16,026 to 19 391, and 33 814 6 per cent. cumulative preference shares of £1 each, fully paid. The committee have also been asked to allow Edmundson's Electricity Corporation's 6 637 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 1 to 6,637, to be quoted in the official list.

Grimsby.—The Corporation on Monday adopted a report of Mr. Vignoles, the electrical engineer, stating that in March there were 2 011 lamps connected with the system, which had since increased to 3,000; others now being wired would bring up the number to 3,407. Since then he had heard of a prospective 700 or 800 more lamps. They had power now for 12,000 lamps. The number of houses using the lights was 55 in March and 68 in May. Consumers taking the light numbered seven in February, 40 on March 31, and 54 on May 2. The total units sold for the six weeks ending March 31 was 3 058; and in the four and a half weeks ending May 2 8,432 units, 5,422 of which was for public street lighting. The income for the first period was £92, and for the second £142; whilst the expenditure in the first period was £120, or a loss of £28, and for the second period £116, or a profit of £26. It was agreed to extend the main in Hainton-avenue at a cost of £66, also to grant Mr. Vignoles £50 in consideration of his services to the Corporation and for extra work done before his appointment as borough electrical engineer. A detailed report of the work referred to was presented, stating that the net amount the Corporation were in pocket through this was £115.

Digitized by Google

Battersea.—The Baths and Wash-houses Committee propose to purchase electric light fittings, etc., for the new baths and wash-houses, in accordance with the estimate of the electrical engineer—viz., £250—which includes fixing.

Chester.—The Lighting Committee have been authorised to lay distributing mains for incandescent public and private lighting in Queen's-avenue and Lee street, at £50; and for the public lighting of St. John's Churchyard, at £25; also to purchase 1,000 yards of distributing main, at £250.

Cheshunt.—The Urban District Council have decided to postpone further consideration of the provisional order under the Electric Lighting Act, and they will in the meantime make enquiries from other local authorities who have obtained orders, with a view to ascertaining what course they contemplate to adopt.

Admiralty Contract.—The Admiralty are proceeding with the fitting of wireless telegraphy to the ships of the British navy. We are informed that they have adopted the "Apps-Newton" coils as the standard pattern, and have placed a large order with Messrs. Newton and Co., of 3, Fleet street, for coils and transmitters.

Worcester.—Colonel A. G. Durnford has held an enquiry into an application of the City Council for permission to borrow £4,950 for purposes of electric lighting. Mr. C. J. Sutherland, electrical engineer, said this extension would cost £4,450, and the other £500 were required for the instalment of 60 incandescent electric lamps in place of gas lamps.

Sutton Coldfield.—At a special meeting of the Town Council last week, convened for the purpose of receiving a report from the Electric Lighting Committee, and for appointing a resident electric engineer, Mr. Trevor Duesbury (chief assistant engineer at the city of Gloucester electricity works) was unanimously elected to the post. There were 104 applicants.

Islington.—The Guardians have appointed a special committee to consider the advisability of wiring for lighting by electricity the St. John's-road and Cornwallis-road Workhouses. The committee is composed of Messrs. Bryen Fricker, Lambert, Mills, Tomkins, Walkley, and Williams. The Borough Council are about to expend £10,530 on the extension of electric mains.

Dollar.—At the last meeting of the Town Council a communication was read from the Board of Trade enclosing provisional order in favour of Messrs. Crompton and Co as to the electric lighting of Dollar, and asking for the remarks of the Council thereon. The order has now been adjusted, and it was thought that any alterations that had been made were in the way of improving the terms of the original order.

Telegraph Manufacturing Co.—The directors, after providing for depreciation and preference dividend for the year ended March 31 last, and placing £6 500 to reserve, recommend a dividend on the ordinary shares for the half-year ended March 31 at the rate of 12 per cent. per annum, and a bonus of 2 per cent. (which, with the interim dividend paid in December last, is at the rate of 10 per cent. for the year, and a bonus of 2 per cent.), carrying forward £7,500. In addition, the premium, amounting to £20 000, received on the issue of new ordinary shares in 1900, has been placed to reserve fund.

Amalgamation of the Yorkshire Electric Power Companies. When the Select Committee of the House of Commons presided over by Sir William Houldsworth resumed the consideration of the two rival Bills—the Yorkshire Electric Power Bill and the South Yorkshire Electric Power Bill—on Monday, Mr. Pember, K.C., announced that a settlement had been absolutely arrived at between the rival companies. Consequently the South Yorkshire Bill would be withdrawn. The main point of the agreement is that three of the directors of the South Yorkshire Company will join the Board of the Yorkshire Company.

Birmingham.—The report of the Electric Supply Committee, with the accounts and balance sheet for the past year, shows a steady increase in the business of the department, the number of units supplied being three quarters of a million more than last year and the cash receipts £10 500 more. On the trading account there is a profit of £27 233 sufficient to pay interest and sinking fund and to allow of £6,600 being carried to the renewal fund. The purchase of the old general hospital site has been completed, and the committee will at an early date consider the question of utilising it for lighting and tramway purposes.

Coventry.—Mr. Jeckell proposes, in order to get through the next winter's load at a minimum expenditure, that certain alterations be made to the present plant by forming a hot well and making up the feed supply from an evaporator. In addition to this, a new grease extractor and surface condenser will be procured, so as to save coal as well as wear and tear of boilers. Last week the works were thrown open to the members of the Coventry Working-Men's Hospital Saturday Committee at their request. The party was shown over the electricity works and the tramways depôt, the engineers in charge explaining the various items of interest.

Parliament.—In the House of Lords during the past week the following Bills were read a third time: Tyneside Tramways and Tramroads, Wigan Corporation Tramways, etc., Leeds Corporation (General Powers), Birmingham (City) Tramways, and Manchester Corporation. The Alkali, etc., Works Regulation Bill passed through committee. In the House of Commons the following Bills have been read the third time: Dublin St. James's Gate Brewery Tramways, Folkestone Corporation, Shannon Water and Electric Power, Bingley U.D.C., Burton-upon-Trent Corporation, and Derbyshire and Nottinghamshire Electric Power. The following have been read a second time: London United Tramways, Cumberland Electric Tramways, and City and South London Railway.

Penge.—A discussion took place at the last meeting of the District Council with regard to the proposed electric light charges. The Clerk reported that in the draft provisional order the maximum price was scheduled at 6d., but in the agreement entered into by the Council with the Lewisham and District Company it was fixed at 4½d. The following resolution was passed: "That this Council strongly objects to the maximum price mentioned in the fourth schedule of the draft provisional order, and instructs its clerk to make the strongest representation thereon to the Board of Trade with a view to expunging the same, and substituting for such prices fixed by the schedule of the agreement between the company and the Council, and should such representation be ineffectual that counsel be employed to appear and oppose the grant of the provisional order."

Stepney.—The Staff Committee are considering a recommendation from the Electrical Committee that Mr. Wright be appointed consulting electrical engineer to the borough of Stepney at a retaining fee of £800 per annum, subject to the following conditions: (*a*) that Mr. Wright's agreement with the late Whitechapel Board of Works be cancelled; (*b*) that Mr. Wright enters into an agreement with the Council whereby his services will be secured at the remuneration above mentioned for a period of five years from Feb. 14, 1091. It is also proposed to reappoint Mr. W. C. P. Tapper resident engineer. As electrical engineer for Whitechapel, he has been receiving £250 per annum, and it is now recommended that he be appointed borough electrical engineer and manager to the electricity department at a commencing salary of £350 per annum, rising by equal annual increments of £25 to £400 per annum.

Woking.—At the last meeting of the Surrey County Council the following report was adopted: "The General Purposes Committee have had before them a representation on behalf of certain inhabitants of the urban district of Woking with regard to increased representation for, and the lighting by electricity of, the Station and Maybury Wards. The committee do not think it desirable that any alteration should at the present time be made as regards the representation of the various wards, and with regard to the question of electric lighting of such ward, they are of opinion that, in view of the fact that the limit of the borrowing powers of the district is being rapidly reached, it is highly possible that such a scheme as that proposed would involve an expenditure which would prevent the execution of other and more important matters of the district. An intimation to the above effect has been sent to the forwarder of the representation."

Hampstead.—The electric lighting accounts show that the amount of the consumers' accounts during the quarter ended at Lady Day was £11 628. 16s. 9d., as compared with £9 346 1s. 2d. for the corresponding period last year. For the year ended at Lady Day the total amount was £32,003 0s. 9d., as compared with £30 652 10s. 9d. in 1900. The lighting of borough roads is before the Lighting Committee, who are considering a letter from the St. Pancras Borough Council, stating that a scheme had been under consideration for the extension of the public arc lighting throughout that borough, and that a number of lamps proposed to be erected fringed that borough and Hampstead, forwarding tracings showing the proposed positions of the new arc lamps, from Savernake-road to Rochford-street, and from Crogsland-road to Primrose Hill-road, and making alternative suggestions for the erection and lighting of such lamps by the two boroughs concerned.

New Issue.—An issue of £100,000 6 per cent. first mortgage debenture stock repayable at £110 on Jan. 1, 1933 is announced by the Kettle River Power Company, Limited, which has a share capital of £220,000. The objects, *inter alia*, of the Cascade Water Power and Light Company (to develop the concession, etc., of which company the Kettle River Company was formed) were to utilise the Cascade Falls of the Kettle River for the purpose of generating and supplying electricity for power, light, and heat in a 40-mile radius from Grand Forks City, Rossland, Cascade, Grand Forks, Phœnix, Anaconda, etc., and also the mines and smelters of both the Rossland and Boundary districts situated in the radius. The prospectus states that the directors intend to commence with the installation of 2,000 h.p., which is estimated to cost about £90,000. At present practically the whole of the local works, including the dam, are reported to have been completed at a cost of about £23 000.

Walsall.—The total number of consumers supplied on April 30 last was 185. The total units generated at the station during the month of April was 32 373. The total output from the main generators was 31 014 units. The total units from the transformers was 23 696. The total units registered on the motors was 29 657. The machinery has been run for 451 hours during the past month. The price of electric current was discussed at the last meeting of the Town Council, and it was stated that it might vary from 6d. to 1¾d. per unit. They had two systems of charging—one for electric light, and another for power. For lighting the charge was 6d. per unit for 1½ hours a day, and 2d. per unit for all other units. The charge for power was 2½d. per unit, and after the first four hours 1d., so that if it was used for eight or twelve hours the price would come down to 1¾d. per unit for power. The price for lighting purposes, if used for a considerable time, might come down to under 3d. per unit.

Lowestoft.—Mr. W. O. E. Meade-King has held an enquiry into the Town Council's application for sanction to borrow a further £20,000 for electric lighting purposes. The Town Clerk explained that the money was required for extensions of mains and plant,

Digitized by Google

and prospective extensions of public lighting; some alterations to the electric light buildings, in order to strengthen the foundations, owing to a settlement; and for some extra work in crossing the harbour, made necessary by the requirements of the railway company. Since this application had been made the Town Council had decided to adopt a scheme to extend the electric light to the whole of the borough. The matter had been before the public, and there had been no opposition to the proposed scheme, which would cost about £10,000. Mr. Hawtayne explained that they proposed to extend the mains for public street-lighting to all parts of the town, and that was estimated at £10,483. Some of that work had been done. The increased plant they desired to secure would practically double the capabilities of output.

Radcliffe.—At the last meeting of the District Council the Clerk reported a statement made to him by the manager of the Lancashire Electric Power Company to the effect that the prices stated in the company's circular were 20 per cent. lower than the maximum price named in the Act; that the company could not make any alteration in the price named therein; and that the directors hoped to be in a position to supply power by Jan. 1, 1903. Messrs. W. Allen, Smith, and Yates were appointed a sub-committee to confer and generally decide upon any action to be taken, and from time to time to give necessary instructions upon and with reference to the prosecution of the Council's opposition to the South Lancashire Tramways Bill now before Parliament. The amended draft agreement between the Council and Messrs. Lacey, Clirehugh, and Sillar was referred to Mr. Clayton. Messrs. W. Allen, Hardman, Lund, and Yates were appointed a sub-committee to consider matters relative to the position, construction, and the general arrangement of the buildings required for the electricity undertaking.

Leeds—Following the gratifying statement concerning the Leeds Corporation tramways, says the *Yorkshire Post*, comes the yearly return of income and expenditure with reference to the electric lighting undertaking, which was municipalised in December of 1898. The figures are not so large as those relating to the tramways, but in view of the coal difficulty, they are considered satisfactory by the committee, who met on Tuesday, under the chairmanship of Mr. J. Green Hirst. The receipts for the year amount to £43,669. 2s. 6d., and the expenditure (including the payment of interest) to £29,154. 16s. 4d., leaving a net profit of £14,514. 5s. 10d. From this sum, however, £7 632. 15s. 2d. has been deducted in respect of sinking fund, so that the surplus of income over expenditure and provision for the future is really £6,881. 10s. 8d. Last year's surplus was £8,500. The difference of £1,621 between the two sums has gone to the coalowners. If it had not been for the high price of coal during the year, the committee would have had a surplus of over £9 000. There are about 2,000 consumers of electricity on the books of the Corporation.

Glasgow.—The following revised scale of charges has been adopted by the Corporation for the year 1901-1902:—For lighting: (1) shops, warehouses, offices, and all other premises, except those specified under heads (2), (3) and (4), to be charged on the demand indicator system, at the rate of 6d. per Board of Trade unit for the first 365 hours' use per annum of the maximum demand, and for all current consumed over this quantity 1d. per unit for 250-volt supplies, 1½d. per unit for 200-volt supplies, and 2d. per unit for 100-volt supplies. (2) Domestic consumers: a uniform charge of 3½d. per unit for 250-volt supplies, and 4d. per unit for 200 and 100-volt supplies. (3) Theatres, halls, and other places of entertainment: a uniform charge of 3½d. per unit. (4) Churches: a uniform charge of 3d. per unit. For motive power: a uniform charge of 1½d. per unit for 250 and 500 volt supplies, and 2d. per unit for 200-volt supplies, subject to such conditions as it may be necessary to enforce for the proper protection of the Corporation. It is not proposed to make any alteration on the rates charged for the current supplied under existing special agreements and for the public street lamps.

New Agencies.—We have been asked to state that the agency which has been held at different times by Messrs. Polland and Co., and also by the Union Cable Company, Limited, for the articles manufactured by the Elektrotechnische Institut, Frankfurt, has now passed solely into the hands of Mr. G. Braulik, and all orders for this firm's manufactures should be addressed to him at 218, Upper Thames-street, where a stock will be kept of Beez pocket volt and ammeters and other specialities of this firm.—We are informed that Messrs. De Grelle, Houdret, and Co., electrical and mechanical engineers, 130, London-wall, E.C., have been appointed sole representatives in Great Britain for the Braunschweigische Maschinenbau-Anstalt for the sale of their dynamos motors, and other electrical manufactures. We have received a list of the standard types of direct current dynamos and motors for belt driving manufactured by Braunschweigische Maschinenbau-Anstalt, and we note that a stock of the open and enclosed type machines will be kept in London ready for immediate delivery, and that most of the sizes may be had in three or four weeks from date of order. Messrs. De Grelle, Houdret, and Co. will supply the trade only.

Colchester.—Mr. W. O. E. Meade-King has held an enquiry into the application of the Council for sanction to borrow sums amounting to £15,900 for purposes of electric lighting. Mr. A. R. Sillar, the electrical engineer, explained that £1,970. 5s. would be required for alterations to machinery necessary upon the proposed doubling of the voltage. The extension was necessary, because they had already a great many more consumers than were anticipated; the change of voltage was necessary because last winter, during a heavy load, the loss was found to be 7½ per cent. They were also to have electric tramways, and for those they would require an increase of power. It was intended to increase the number of accumulators, to rewind two motors, and make alterations necessary for the higher voltage, etc. The rest would be for generating station extensions, building an underground water-feeder, purchasing new engine, feeder for the new barracks (£1,260), etc. The second item of £3,900 was for the purchase of the Osborne-street property adjacent to the electric light station, although the whole amount would not be immediately required. Without a portion of it, however, they could not make the necessary alterations. Mr. H. Goodyear, the borough surveyor, said the buildings alone were worth £2,000.

Cardiff.—The last report of Mr. A. Ellis shows that there are now 401 customers, with a consumption equivalent to 40,022 8-c.p. lamps (an increase of 45 per cent. on the number in the corresponding month of last year). During the month 2,668 8-c.p. lamps were connected. The number of units generated during the month was 72 579, an increase of 47 per cent. The calculated income for the month was £160. 12s. 6d. for street-lighting and £557. 11s. 6d. for private lighting, a total of £718. 4s. (against £514 last year, an increase of 39 per cent.). Messrs. Thomas Owen and Co., Limited, of Ely Paper Works, have decided to accept current from the Corporation, which will increase the income of the department to the extent of between £400 and £600 a year. Mr. Ellis stated on Tuesday that the estimated revenue for the year ending March 31 last was £9,969, while the actual revenue was £11 670. It had been reported that last year they had sustained a loss of £1,000. The loss for the year ended March 31, 1900, was £1,700. For the year ended March 31, 1901, the loss was about £300. In each case, however, it was after paying out between £5,000 and £6 000 on the capital and interest repayment account. In view of that they really made a profit last year, and were working at a profit at the present time.

Croydon.—Under the original lighting scheme of the Council 61 rectified arc lamps were installed. It has now been found, however, advisable to extend this system, but the recent additions are enclosed arc lamps, especially of the Lewis type, and these have been found to be a great success. There are already 152 of this type of lamp in various parts of the town, and as soon as the new tramway track is completed the whole route from Norbury to Purley (a distance of about six miles) will be lighted by these lamps at a distance of 60 yards apart. Considering the conditions under which the supply of electricity is being carried on, and the heavily-handicapped state in which it is working, due to the very large capital outlay required to reach the outlying districts, and, therefore, heavy sinking fund and interest, it is generally considered that the financial results of the past three years' working are very satisfactory. It is, of course, impossible to give at present the final correct profits for the year ending March 25, 1901, but the following figures will approximately show the result of the past year's working: cost of production, 1 536d. per unit; average price charged to consumers 4·44d. per unit; gross profits, £8,390. Current for lighting purposes is generated at 2,000 volts and transformed down to 200 volts at sub-stations, at which pressure it is delivered to customers.

Sell's World's Press, 1901.—The publishers, in presenting their "coming-of-age number," state that practically the whole book was burnt in January last in the disastrous fire in Pentonville; hence the delay in publication. Articles on the last century's newspapers and British journalism of 100 years ago take up a considerable portion of the first portion. The article "Journalism and the South African War," accompanied as it is by portraits of upwards of 20 of the leading war correspondents and the effect of the war on the newspaper world generally, will be found of more than usual interest, though it might have been more complete, for we miss amongst the portraits of Colonial scribes one Donald Macdonald, the representative of the *Argus*, the leading Australian daily, and the author of *the* book on "The Siege of Ladysmith." There are also many other articles in connection with the papers published in British possessions dealing with imports and exports, and their influence upon the trade of the British Empire, together with portraits, diagrams, maps, etc. Short summaries are given of each foreign country in regard to their various industries, chief physical features, productions, etc. The tariff charges of America and Canada will be valuable to business men as well as to journalists. The lists of papers, magazine lists, and class newspapers, which have been revised up to date, are easy of reference.

Southend Elevator.—We have already referred to the negotiations by the Highways Committee with the Reno Inclined Elevator Construction Syndicate for the construction of an elevator from the esplanade to the cliffs The Town Council have now agreed, on the suggestion of that syndicate, that a license be granted to Mr. W. H. Aston, of Eagle Wharf-road, for the construction of a Reno inclined elevator for the purpose of conveying persons from the lower esplanade to the top of the cliffs, and that the site be on the strip of land immediately adjoining the west side of the steps leading to the Jubilee jetty; the license to be for 10 years; the licensee to pay to the Corporation a royalty of 20 per cent. of the gross takings, with a minimum rent or royalty of £125 per annum; the elevator to be run daily in each year from Good Friday to the end of October, between the hours of 10 a.m. and 10 p.m., and at such additional times as the licensee may desire; the charge for each person to be 1d.; the licensee to take from the Corporation electric energy for working the elevator, and pay therefor at the rate of 3d. per unit; the Corporation to have the right of purchasing the elevator at the end of the third year of the term for the sum of £3,250, at the end of the seventh year for the sum of £2,250, and at the end of the tenth year for the sum of £1,500; the Corporation to be at liberty to determine the license upon breach by the licensee of any of the terms or conditions of the license.

PROVISIONAL PATENTS, 1901.

MAY 13.

9840. Improvements in meter interrupters for use with induction coils. Herbert Charles Newton, 3, Fleet-street, London.

9844. An electrical transmission dynamometer and tachometer. Charles Vickery Drysdale, Clairville, Hadley-road, New Barnet.

9865. Improvements in apparatus for opening and closing electrical circuits. Joseph Devonport Finney Andrews, 75, Fulham Park-gardens, London.

9882. Improvements in and relating to electric arc lamps. George Munroe Lane, 36, Chancery-lane, London. (Complete specification.)

9915. Improvements in or connected with electric motors. Walter Herbert Flood and Alfred Edward Honey, 4, South-street, Finsbury, London.

9916. Improvements in collecting brushes and holders for dynamo-electric machines. Walter Herbert Flood and Alfred Edward Honey, 4, South-street, Finsbury, London.

9925. Improvements in the working of induction coils and other apparatus with alternating and pulsating currents. Herbert Charles Newton and Russell Stuart Wright, 3, Fleet-street, London.

9926. Improvements in and relating to transmission dynamometers. Ernest George Coker, Engineering Building, McGill University, Montreal, Quebec, Canada.

MAY 14.

9927. Improvements in or relating to the deposition of metals or compounds. Sherard Cowper-Coles and Co., Limited, and Sherard Cowper-Coles, 82, Victoria-street, Westminster, London.

9929. The electric revolving brush. Alfred Ernest Thomas and Joseph Buckley, 6, Exchange-chambers, Birmingham.

9933. Improvements in or connected with trolley arms and in attaching same to the outside covers of electric tramcars. Charles Henry Wilkinson, Market-place, Huddersfield.

9959. Improvement in incandescent electric lamp globes. Ernest Böhm, 99, Cannon-street, London.

9962. Improvements in or relating to the pole-pieces of dynamos and other magneto-electric machines. Albert Stockton and Sidney Harper Heywood, 70, Deansgate, Manchester.

9967. Improvements in electric cables. John Dunckley Gould, 53, Chancery-lane, London. (Complete specification.)

9993. An improvement in electrical lighting as applied to advertisements and the like. William Oscar Jennings, 19, Surrey-street, Strand, London.

10010. A new form of standard electric resistances for small and large current strengths. Hans von Kramer and Francis Greenwich Sharp, 115, Stirling-road, Glasgow.

MAY 15.

10053. An improved trolley wheel for overhead wire systems of electric traction. Edward May Munro, Henry Brecknell, and Hugh Innes Rogers, Lloyd's Bank-buildings, Bristol.

10062. Improvements in moving-coil electrical measuring instruments. August Eckstein and Frank Panter, Peel Works, Adelphi, Salford, Manchester.

10063. An appliance preventing trolley wheel from leaving overhead wire in electric traction. Matthew Fitzmaurice Tilson Deane, 32, Garville-avenue, Rathgar, Dublin.

10080. Improvements in or connected with apparatus for wireless telegraphy. Henry Richard Belcher Hickman, 33, Chancery-lane, London.

10088. Improved apparatus for treating affected parts of the body with heat, light, or electricity, in certain cases simultaneously. Ignaz Timar, 55, Chancery-lane, London. (Complete specification.)

10102. Improvements in electrical switches. Evered and Co., Limited, and Charles Holt, 7, Staple-inn, London.

10120. Improvements in electric telegraphy. Alexander Muirhead, 323, High Holborn, London.

MAY 16.

10130. Improvements in life guards for electric tramcars or similar vehicles. Thomas John Kendrew, 8, Lombard-chambers, Bixteth-street, Liverpool.

10166. Improvements in printing telegraph receivers. Alfred Julius Boult, 111, Hatton-garden, London. (The Joy Printing Telegraph Company, United States.) (Complete specification.)

10188. Improvements in electric indicators for use in sectional telephone circuits. Charles Mark Jacobs, 70, Chancery-lane, London.

10191. Improvements in, and in apparatus for, the manufacture of the plates of electric accumulators. Arsène d'Arsonval and Georges Vaugeois, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Dec. 27, 1900, being date of application in France.)

10202. Improvements in safety devices for electric tramcars and other motor-driven vehicles. Alexander Rutherford, jun., 6, Lord-street, Liverpool.

10206. Improvements in electric railway systems. Baptistin Cruvellier, 72, Cannon-street, London. (Complete specification.)

10215. Improvements in and connected with casings or coverings for electric conductors in buildings Joseph Henry Golding and Charles Alfred James, 47, Lincoln's-inn-fields, London.

MAY 17.

10228. A new or improved combined system of electric lighting and fire alarms, and appliances connected therewith. Charles Cartwright Metcalf, 50, Oldfield-road, Sale, Cheshire. (Harry Cecil Blackwell, Russia.)

10238 Safety device for overhead electric wires (The Littler and Creary). John William Littler and Robert Wilson Creary, 62, Navigation-road, Broadheath, Cheshire.

10249. Improvements in or relating to electrical ignition apparatus for internal-combustion motors. Charles Alexander Hamilton, 18, Hertford-street, Coventry.

10250. An improved safety device for preventing the breakage of telegraph and telephone wires and the like. Edward William Martland, 5, John Dalton-street, Manchester.

10275 Improvements in controlling electric motors. The British Thomson Houston Company, Limited, Bush-lane House, Cannon-street, London. Maxwell W. Day, United States.) (Complete specification.)

10295. Improvements in electrically-operated desk-fans. Car Schwabe, 6, Lord-street, Liverpool.

MAY 18.

10345. Improved method of and means for forming joints on or connecting electric wires. James Lightfoot and Charles Monkman, 8, Quality-court, Chancery-lane, London.

10357. An improvement in electric conductors. Siemens Bros. and Co., Limited, and Frank Jacob, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

10374. Improvements in or relating to step-by-step telegraphic apparatus. William Morris Mordey and Walter Samuel Steljes, 46, Lincoln's-inn-fields, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on June 8.

1900.

8779. Electric switches and fuses. James Whitcher, Arthur Henry Lea, and Daniel John Evans, and Edward Paul Toller (executors of the late Cecil Herbert Warren).

9492. Ceiling roses and other similar electrical connections. Douglas.

9534. Method of starting and regulating multiphase-current motors. Boucherot.

10542. Electric couplings. Oppenheimer. (Actiengesellschaft Mix und Genest.)

10545. Switches or keys for electric lamp-holders. Oppenheimer. (Actiengesellschaft Mix und Genest.)

12716. Electric switches. Dale.

12743. Method of and apparatus for the local application of electrical treatment to the human body. Behrendt.

12827. Electrical switches. Bartlett and Robinson.

12944. Electrical switch. Clayton, Bell, and Berry.

12973. Indicator for high electrical tensions. Siemens Bros. and Co., Limited. (Siemens und Halske Actiengesellschaft.)

13014. Fuses or cut-outs for high voltage circuits. Oppenheimer. (Actiengesellschaft Mix und Genest.)

13015. Insulated bases for switches. Oppenheimer. (Actiengesellschaft Mix und Genest.)

14409. Electric meters. Harris.

15642. Electric incandescent lamps. Hollub and Mignal.

23675. Process and apparatus for obtaining electric current. Britzke.

1901.

2659. Electric arc lamps. Helios Upton Company and Spencer.

3192. Electric furnaces. Jurie.

7150. Electromagnet motor. Englehardt, McNelly, and Gallert.

7547. Incandescence electric lamps. Lake. (Smithers.)

7783. Controllers for electric motors. British Thomson-Houston Company, Limited. (Potter.)

7834. Insulators for electric conductors. Bennet and Johansson.

NOTES.

Book Received.—From Messrs. Longmans, Green, and Co., of Paternoster-row, E.C., we have received a copy of Mr. Wm. J. Hopkins's latest work on "Telephone Lines and their Properties." The book is published at 6s.

Electrical Engineers Volunteers.—The ceremony of opening the headquarters of the corps of Electrical Engineers (R.E.) Volunteers, of which the Right Hon. Lord Kelvin is hon. colonel, will take place to-morrow (Saturday) afternoon at four o'clock. The new headquarters are situate in Regency-street, Westminster.

Personal.—At a committee meeting of the Crawford Municipal Technical Institute, Cork, Mr. Edward A. O'Keeffe was unanimously elected to the post of head science master and organising secretary from 48 applicants. He is best known in connection with Finsbury Technical College, where he spent many years as senior demonstrator in the department of electrical engineering and applied science under Prof. Silvanus P. Thompson.

New Anglo-German Cable.—The landing of a new submarine cable between England and Germany at Bacton, on the Norfolk coast, has been successfully accomplished. The German cable ship "Von Podbielski" was engaged on the work, and having safely landed the English end of the line she left for Germany, paying out as she went. This makes three cables between Bacton and Emden, by way of Borkum Island, and brings up the number of wires to 12. The two former cables, laid in 1891 and 1896, were installed by English telegraphic staffs. This last addition was laid by the Norddeutsche Sea Cable Company of Emden.

American Institute's Transactions.—We have to acknowledge the receipt of the *Transactions* of the American Institute of Electrical Engineers for April last. This issue contains papers on "The Distribution and Conversion of Received Currents," by Mr. H. G. Stott; "The Transformer for Measuring Large Direct Currents," by Mr. H. J. Ryan; and "Electricity in Mountain Mines," by Mr. F. W. Brady. It also gives the discussions on two other papers—viz., "Floy on the St. Croix Plant" and "Behrend on Mechanical Forces in Dynamos." The proposed constitution of the institute is set out at the end of the volume.

Underground Moving Platforms. — The great success which attended the working of the moving platform operated by Westinghouse motors at the Paris Exhibition, has led the Paris authorities to consider the installation of another electrically-controlled moving platform. The novel feature of this installation, if it be ultimately decided upon, is that it will be built underground. The proposed track is to run under the Avenue de l'Opera, the Boulevards, Boulevard Sebastopol, Rue Turbigo, and Rue de Rivoli, a distance of just upon seven miles. The line is to consist of four platforms; the first will be stationary, the second will move at a speed of about three miles an hour, and the third and fourth at the rate of about six or eight miles an hour respectively.

Medical Exhibition.—The Medical Exhibition which was opened this week at the Queen's Hall, Langham-place, under the auspices of the Medical, Surgical, and Hygienic Exhibitors' Association, is the fifth of its kind, and may now be regarded as a well-established annual fixture. The latest developments of surgical instruments and appliances, hospital fittings, etc., are to be seen here, affording an excellent opportunity of comparison between the numerous specialities of the different firms exhibiting. Among the many interesting exhibits we noticed in particular the complete equipment of Röntgen coils and apparatus as fitted on board the "Princess of Wales" hospital ship and in the Yeomanry and Scottish Red Cross hospitals. This secured especial attention. The exhibition, which closes its doors to the public this (Friday) evening, has proved at least as successful as any of its predecessors.

Austrian Telephone System.—The city of Vienna is particularly fortunate in possessing an immense system of local telephones, and, what is more, the tariff, to say the least, is modest. In all there are close upon 20,000 telephones in Vienna, and for an annual payment of 10 guineas subscribers are not only connected with this extensive local system, but also with Berlin (450 miles), Lemberg (500 miles), Dresden, Budapest, and over 200 other towns in Austria-Hungary. Each of these places, many of them small towns with a few thousand inhabitants, has an excellent local telephone service. We understand that a scheme is now being considered by the Ministry of Commerce by which every house in Vienna could be supplied with a telephone. Vienna is built on the flat system, and there are rarely less than 20 families living in one building. It is therefore proposed to establish a small telephone "central" in each house.

Trend of Invention.—The remarkable progress in electric traction work within the last few years is given full prominence to in the report for 1900 of the Comptroller-General of Patents, Designs, and Trade Marks, just issued. The trend of invention in this direction has truly been most marked, and, according to the report before us, in the year under review there was an exceedingly large increase in the number of inventions relating to electric traction. The London electric underground railways and the numerous electric tramways now working in this country, the report states, have aroused considerable public interest in electrical subjects. Over 100 applications were made during the year by one firm of electrical engineers alone. Outdoor seats for tramcars, etc., claimed a large share of attention from inventors. Applications relating to motor-cars were numerous, but showed little increase, while those for cycles decreased, especially at the beginning of the year. There were several applications for military inventions, but no increase in this subject could be traced directly to the war.

Electricity and Seed Life.—The experiments described by Dr. A. D. Waller before the Royal Society a month ago raise a number of interesting speculations. The author experimented with a number of seeds and vegetables, and claimed that he was able to tell from the results of these experiments whether the seeds were alive or not. He placed the beans or other seeds to be experimented with between a pair of moist electrodes, and sent a discharge through the same by means of a condenser which had been previously charged up by a couple of Leclanché cells. After the discharge had taken place the bean was connected to a sensitive galvanometer. The author claims that if the bean was alive, the discharge obtained was very much higher than if the seed were dead. In the first case, if the bean were alive about 75 milli-volts were found, whereas if the seed were dead the voltage was hardly appreciable, not being more than one milli-volt. From the information before us we do not quite know how the author was able to determine beforehand if the seeds were alive or not, as we gather that the experiment itself was apt to destroy life if it existed.

The Telegraph Service.—In certain quarters the financial failure of the Government telegraph service is held up as an instance of the incapability of the Post Office

Digitized by Google

authorities to carry on their affairs in a businesslike manner. This, however, is a mistaken idea. It must not be forgotten, in the first place, that the sixpenny telegram was introduced into this country as a public convenience, and not for the purpose of profitmaking. Within the last 30 years the telegraph system of the United Kingdom has been increased by five times as much. In 1870 there were 60,000 miles of wire, now there are 300,000, and in the same period the number of instruments has been raised from 4,000 to 32,000, the value of the system having increased from about £5,000,000 in 1870 to £40,000,000 in 1898. When it is considered that the whole cost of this development was defrayed out of the revenue, the capital account remaining unaltered, it will be seen that the case does not warrant the pessimistic view which has been taken of it, especially among the opponents of municipalisation and State ownership. In spite of all that may be said, we are getting a telegraph service in this country at less than half the cost of the United States service, besides having a national asset which is always increasing in value.

Unofficial Advice.—We regret to see that in certain instances where new electrical work is proposed to be carried out by local authorities, certain professional engineers are giving advice without their names appearing as the authors of such advice. In both of the two instances we have in mind the schemes have been tramway undertakings, and in each case a consulting engineer has been retained to advise the corporation as to the best means of carrying out the electrification of the tramways and the supply of power for the same. When the schemes suggested by these engineers have come before the town councils in question, there has been strong evidence from the debate that the leaders of the opposition have been coached up by outside experts, whose names are never mentioned, although reference has been made to the fact that the opinions expressed by the speakers are not their own. It is, of course, only right that when large sums of money have to be spent the town should have the most able advice as to the best results which can be obtained, and also as to the least cost at which these results can be secured. It is not, however, right that an engineer who has presumably not been selected as the most capable man to advise the corporation should afterwards go out of his way to give advice which tends to hamper the carrying out of the work.

The Manchester-Liverpool Express Railway.—The promoters of the so-called monorail railway between Manchester and Liverpool have succeeded this year in getting their preamble proved before the Parliamentary Committee. This, we consider, is an evidence of what can be done by untiring perseverance. The Bill in question has been strongly opposed by a number of vested interests for the last few years, and yet has at last succeeded in getting through committee stage. When before the committee certain experts raised the question, which we have had to call attention to at various times, as to the real advantage of the so-called monorail in view of the fact that a number of guide rails have to be employed to keep the train in balance. There are actually, we believe, five rails in all, although the one rail bears the whole weight of the train. In our opinion it remains to be proved that this construction really gives any advantage over an ordinary railway if laid out with the same care in avoiding curves, etc. The Bill has yet to get through its third reading in the House of Commons, while the crucial point as to whether the promoters can obtain the requisite capital to start the line is a still greater problem to solve. We do quite concur with the promoters, however, that electrical driving is the essential feature for trains which are to be run at the high speed of 120 miles an hour.

Sir Courtenay Boyle's Successor.—Mr. Francis J. S. Hopwood, C.B., C.M.G., whose appointment as permanent secretary to the Board of Trade, in succession to the late Sir Courtenay Boyle, was notified on Wednesday, entered the Board of Trade as assistant law clerk in 1886. Two years later he became assistant solicitor, and subsequently private secretary to the then president, Sir Michael Hicks-Beach. When in 1893 the late Sir Courtenay Boyle succeeded Sir Henry Calcraft as permanent secretary, Mr. Hopwood was appointed secretary to the railway department, which post he filled until his present promotion. In that department he has been especially connected with legislation for the promotion of light railways, the development of electric traction, the prevention of accidents to railway servants, and the regulation of their hours of labour. He was also a member of Mr. Asquith's Commission on the Metropolitan Cab Service, and a British delegate to the International Railway Congress in 1895. Mr. Hopwood has on several occasions been entrusted with official business in the United States, Canada, and Newfoundland, and it will be remembered he took a prominent part in the settlement of the Taff Vale Railway dispute last year.

National Electrical Contractors' Association.—A meeting of the promoters and supporters of this movement was held at the offices of the secretary on Tuesday, when the chairman (Mr. H. Bland) delivered a most interesting address, dealing with the need for such an association and the good work which had already been done by the local associations in existence up and down the country. In the discussion which followed, encouraging reports were made by representatives from provincial associations, and a number of points affecting the well-being of the association were gone into. A resolution was then unanimously adopted to the effect that: "Having regard to the desirability of forming a national association for the purposes, *inter alia*, of protecting and consolidating the interests of electrical contractors in Great Britain and Ireland, it is hereby moved that the representatives of local associations and others present at this meeting hereby form themselves into an association to be called the National Electrical Contractors' Association." A large and influential general committee representative of England, Scotland, and Ireland was appointed, and it will be one of the duties of this committee to use its best influence in forming local associations in centres where they do not already exist, so that the movement may become universal throughout the United Kingdom.

Pipe-Line Transportation.—The current number of *Cassier's Magazine* contains an article under this heading, in which the extent to which the pneumatic tube principle will be employed to expedite transportation, now entirely dependent on steam locomotives, is considered. It does not seem altogether unreasonable, the editor says, to think that just as the miles of tank cars loaded with oil, which were seen in former years, have disappeared, and that commodity is now sent hundreds of miles through pipe lines, so may coal, grain, and ore be sent speeding through tubes to central depôts for local distribution. In the matter of coal transportation, in fact, just such pipe-line conveyance was tried experimentally something like 10 or 12 years ago by the late W. C. Andrews, of New York—the coal for that purpose being ground into powder, mixed with water in sufficiently large proportion, and carried through the pipes in semi-liquid form. At the delivery end of the pipe line there were to be settling chambers for

Digitized by Google

the mixture, enabling the water to be drained off and the coal paste, if it may be so termed, to be pressed into cakes and dried for consumption. The project, however, did not extend beyond the experimental stage. In woollen mills, on the other hand, it is a common thing to blow wool from one building to another through pipes by means of fans, and in potteries, too, clay paste is frequently carried from one point to another through pipes. There is, thus, the article concludes, a fairly good beginning for pipe-line engineering with solids.

Whit Monday Traffic Returns.—Of the many returns prepared showing the enormous extent of suburban traffic on Whit Monday conveyed by tramways, omnibuses, and underground railways, perhaps those supplied by the London United Tramways Company with reference to the traffic on the new electric trams in the West of London are the most striking, and constitute a record. From seven o'clock in the morning until an hour after midnight a one-minute service was maintained on the lines westward of Shepherd's Bush and Hammersmith, during which time no less than 209,636 passengers were carried over the nine miles of route now being worked by electric traction. The success of the undertaking may be judged from the fact that for the corresponding day last year, when the horse cars were in operation, the total was 81,500, and for the Easter bank holiday, when the electrical system was in operation for the first time, 164,000 passengers were carried. During the evening the pressure was so severe that gangs of labourers employed upon the Ealing and Southall extension had to be requisitioned in order to regulate the traffic, and were placed in cordons around the trams at the termini and stations. Turning to the Central London Railway, we find that 128,000 passengers were conveyed over the line, including 40,000 bookings at Shepherd's Bush Station. The only other electric railway at present in operation in the Metropolis (the City and South London Railway) shows a total of between 30,000 and 40,000 passengers carried during the day.

An Electric Typewriter.—In the *Electrical World* of New York Mr. B. C. Washington, jun., has an interesting description of an electric typewriter, a large number of which machines are now in daily use in Washington. The amount of current required to operate the machine would appear to be very small. In Washington current is as a rule taken from circuits of the city light and power company, while in other cases a battery of primary cells is the means of securing power. Again, two small storage battery cells also furnish ample current for operating the machine. The workings of the different parts of the typewriter, which is of simple mechanical construction, are extremely quick, and greater speed and better work are among the results claimed. The most satisfactory feature of the invention is that the running legato touch is obtained in a type-bar machine, a point which had not been accomplished before. Other advantages claimed for this machine are that there is but one electromagnet for operating all the type bars, one motor frame, one contact frame, and but one place where the electric circuit is closed and opened. Again, the power of the electromagnet is under ready control, and a copy of perfectly uniform distinctness is thus secured. These machines can be operated by direct or alternating current, by a storage or primary battery, as stated above, and can be regulated to take current ranging in E.M.F. from 4 to 500 volts. A very weak current is ordinarily used. A touch of from $2\frac{1}{2}$ to 4 or 5 ounces is said to be quite sufficient to operate the keys. The operator, therefore, is relieved practically from all physical work, his services being required merely in the capacity of a director.

Velocity of Ions.—Some short time ago there appeared in the *Physical Review* an article by Mr. C. D. Child offering an explanation of the electric arc on the assumption that the current in the arc is carried by ions. In another article on the subject in the same journal Mr. Child refers to a method of investigating the arc further. The experiments carried out by the author may be summarised as follows: A study of the rate of discharge from an arc to a neighbouring body showed that under varying conditions of difference of potential, distance, and current in the arc itself, the positive ions drawn from the arc moved more rapidly than the negative ones. This is not to be explained as an effect due to ultra-violet light or any phenomena previously studied. The positive ions from a carbon placed in an oxy-hydrogen flame also moved the more rapidly. In cases of an arc between metals the negative ions again moved the more rapidly. While this work did not prove that the positive ions in the arc itself moved more rapidly than the negative ones there, it is in every respect consistent with such a hypothesis, and it shows that it is possible for the positive ions to do so. The question why the positive ions here showed this peculiarity is, of course, entirely unanswered. In all the cases so far studied we have had carbon, and also a very high temperature. It would at present be useless, the author concludes, to speculate as to whether this phenmenon is to be ascribed to one or the other of these facts, or to some one entirely different. In time the author hopes to publish further experiments bearing on this point.

Alternate-Current Meters.—A goodly number of various types of alternating-current meters were exhibited in the Paris Exhibition last year, and these were experimented on by Mr. Janet, who gives his results in the *Bulletin de la Société Internationale des Electriciens.* In an introduction he points out that while for a number of years there has not been much change in the construction of direct-current meters, a number of new types of electricity meters for working on alternating-current circuits have been devised. With these improvements has come a reduction in the no-load losses in the meters, and also improvements in the construction, which enable them to start with exceedingly small currents. For instance, the author found out that the electricity meters of 1,000 watts capacity exhibited at the exhibition had on an average a no-load loss of about three watts. The average starting current for this size of meter came out to about 90 milliamperes. These figures show a great improvement on the earlier types of alternate-current meters. The author considers, however, that the low starting current is too often got by introducing a few shunt-turns to overcome the starting resistance. These turns are apt to produce inaccurate readings, for instance, in places where there is a considerable amount of vibration. In such cases it sometimes occurs that the meters will continue to run on the shunt alone, which makes a considerable error in the course of a year. On the other hand, a meter without the shunt-turns is likely to read against the supply company, as it is apt to stand when only one 8-c.p. lamp is switched on. The author also deals with the best way of overcoming other errors arising in alternating-current meters to be used on circuits of low power factors.

Electromobiles.—So far we have not had the pleasure of recording the financial success of any of the various electric vehicle enterprises which have been launched in different parts of the world within the last few years. We have, however, referred to two or three failures, notably

Digitized by Google

the Boston and the Paris electric cab companies; and we are glad, therefore, to note that "the earnings of the New York Electric Vehicle Transportation Company have been steadily increasing," and that "the company has now reached a point where the directors deem it wise, in the protection and furtherance of its interests, to immediately make provision for the better establishment of its present business and the proper meeting of future requirements." At least, this is the state of things as set out in a circular to the stockholders of the company announcing an assessment of £2. 10s. per share. That success is attending the undertaking of the company is undoubted, in face of the fact that "the demand for vehicle service has been constantly in excess of the vehicle equipment." Again, the new main station at Forty-ninth-street and Eighth-avenue, and the various sub-stations conveniently located at necessary points throughout the city, have shown most satisfactory results. Additional stations, it is stated, must be provided before next winter, delivery wagons facilities in particular being required. The Buffalo branch of the company, too, is proving a desirable investment, and considerable extensions are there in progress. This, however, is more especially to meet the very profitable demand that is anticipated during the Pan-American Exhibition. A new type of battery giving, it is claimed, more than double the mileage on one charge of electricity has been comprehensively experimented with, and after operations covering 25,000 miles has developed but few defects.

Localising Faults in Tramway Conduits.—In the issue of *L'Industrie Electrique* for the 25th inst. we notice an interesting description of a method developed by Messrs. G. Claude and L. B. de Villiers for localising insulation faults in conduits for electric tramways. The great advantage of the system used is that the faults can be localised while service of cars is still going on. The method depends for its success on the fact that the resistance of the tramway conductor is exceedingly high when the frequency of the testing current is as high, as is the case with currents generated by the discharge from Leyden jars. The apparatus consists of the usual Ruhmkorff coil for producing these oscillatory discharges, and the discharge is made to pass through two condensers and then through a solenoid. Two points of this solenoid are then connected, the one through a hot-wire ammeter on to the tramrails, and the other through a condenser on to the contact rail. The object of the condenser is to prevent any continuous current from the tramway conductor passing back through the solenoid. The whole of the apparatus is mounted on an ordinary tramcar, which is then taken along the track. It is said in the article that when the two contacts rest on the rails at from 20 to 30 yards distant from the voltage, the ammeter is not appreciably deflected, owing to the high resistance of these conductors to the oscillatory current. As the car moves over the fault, however, the deflection of the ammeter increases to a maximum value, which maximum is reached when the brushes are just over the point of low insulation. The method works exceedingly well in practice, and is one which will commend itself to tramway engineers who have to do with the conduit system of electric traction.

Electric Light and Heat Bath.—Dr. F. C. Eve, house physician at the Royal Infirmary, Hull, describes in the *Lancet* a simple form of electrical light and heat bath, which appears to have met with considerable success in practical use. The apparatus consists of three 32-c.p. lamps fixed on an aluminium base, and protected by a wire cage from contact with the skin of the patient or with the blankets forming the walls of the chamber. A piece of flexible wire connects the apparatus with the socket of any domestic lampholder, the cost of the current coming out at about 2d. per hour. The apparatus may be used to heat up either a single limb or the whole body, and eight cases of chronic joint disease have been treated by it, with the result that mobility has been markedly increased and pain almost entirely relieved in each instance. The *modus operandi* is this: The limb, the apparatus, and a thermometer are all placed together under a chamber formed of several blankets thrown over a cradle. The limb is covered with a single layer of lint to prevent any risk of scorching a particularly tender skin. This is gradually withdrawn in successive baths. The temperature of the chamber rises in from 15 to 30 minutes to from 200deg. to 250deg. F. Under this treatment, Dr. Eve says, the limb sweats copiously, and a general perspiration is induced. As a rule the body temperature rises two or three degrees, especially when the whole body is treated. In the eight cases of rheumatoid anthritis referred to, the ages ranged between six years and 60 years, and the results obtained as regards pain and stiffness are accepted as being very satisfactory; but in other cases which have come under Dr. Eve's treatment it was found impossible to obtain improvement beyond a certain point. The author's conclusion, however, is that at the end of a bath a stiff joint is much more supple and less tender, so that an excellent opportunity for massage is afforded.

The Westinghouse Company.—We gather from notices which appear in our American contemporaries that the Westinghouse Company has recently opened its works to the editors of all the numerous papers of the States. In view of the fact that these works are not, as a rule, open to English visitors to the States, a perusal of the report of those who went through the works on this occasion will be of interest. What strikes us most in the articles before us is the great size of the individual machines which are now in course of construction. Certain of these are for the Manhattan Railway, contracts for which equal to one million sterling have been placed with the Westinghouse Company. For instance, the firm are supplying no less than eight 5,000-kw. three-phase generators to work at a voltage of 11,000. They have also under this same contract to make 28 1,500-kw. rotary converters and the step-down transformers required in connection with the same. In view of the large size of the first-mentioned machines, extensions have had to be made in the building, as in the older structures there was not sufficient height under the travelling cranes. A good part of the machine tools in these new extensions will be of the portable type, the tool being taken to the work instead of the work to the tool. The portable machine tools are being driven by three-phase induction motors supplied from the generating station on the works. We gather also that the 15 large machines for the St. Lawrence Power Company are now well under way in the shops, as the first of these generators is almost ready for delivery. In fact, a glance down the list of the machines of over 1,000 kw. capacity now going through the Westinghouse works makes us wish that the English manufacturers were having a share of the large orders now being placed in America. This, of course, is not likely in view of the present high tariff, but we see no reason why our manufacturerers should not reorganise their works so as to prevent the converse taking place so frequently in the future as it has done in the past.

Dublin Local Section.—The first report of the committee of the Dublin Section of the Institution of Electrical Engineers covers the period from the inauguration of the section up to the present time. At the outset reference is

Digitized by Google

again made to the irreparable loss to the Institution by the death of the first chairman of the section, Prof. G. F. FitzGerald. He was most keenly interested in the welfare of the section, he was enthusiastic as to the advantages to be derived from the promotion of it, and he acted on the provisional committee charged with the preliminary arrangements. Altogether 10 general meetings have been held since the inauguration of the section. A conversazione was given on Nov. 29, 1900, and was very successful. Seventy-seven exhibits were mentioned in the programme, but the actual number was much greater. During the evening Prof. FitzGerald gave a most interesting demonstration of rotating magnetic fields, and the committee feel that this has a pathetic interest in that it was his last public lecture. The average attendance, including visitors, was about 40, and members would do well to remember that, by their presence and assistance at the meetings, they have it in their power to make the work of the section a success or otherwise. The committee express their sincere hope that members will freely come forward with papers during the next session. Since the formation the membership has increased from 41 to 58. The number of new members of all classes was 28, and the difference is caused by members leaving the area of the section. The committee desire to record the indebtedness of the section to the council of the Royal Dublin Society for their kindness in permitting the section to hold meetings at the society's offices. The committee also desire to thank the council of the Royal College of Science and Monsignor Molloy for a similar hospitality on certain occasions. The constitution of the committee for the ensuing year is as follows: Prof. W. F. Barrett, F.R.S. (chairman), Messrs. J. W. Towle (vice-chairman), C. A. Burge, C. P. C. Cummins, F. Gill, Monsignor G. Molloy, D.D., D.Sc., Messrs. A. E. Porte, W. Tatlow, P. S. Sheardown, F. T. Trouton, D.Sc., F.R.S., G. F. Pilditch, and M. C. Olsson.

Metropolitan District Railway.—The last we have heard concerning the electrification of the Inner Circle is not of a character which does credit to the companies owning this line. It is to the effect that contractors are now being asked to send in new tenders on revised lines. By this we presume is meant that the directors of the two companies have now agreed to a certain extent as to the system which they will adopt, and are asking the various contracting firms to tender all on the same lines. While this is most desirable in order that the line may be equipped at competition prices, we have to object most strongly to the way in which the directors of the companies have arrived at what they consider to be the best system. In the first instance, when they asked for tenders, they left every detail of the equipment in the hands of the parties tendering. While this left the contracting firms a free hand to make use of standard articles, it also left with them the selection of the actual system of generation and distribution to be used. The question also as to whether locomotives should be used, or if motors should be placed on a number of cars, had also to be decided by the contractors, who were desired to give every information as to the working of the system they proposed to adopt. In consequence of the freedom given to the contractors, they had in every case to work out full details themselves, and to expend three or four times the amount of skilled labour on the preparation of their tenders which would have been required if they had all to tender on a firm specification. In other words, if the companies, in the first instance, had gone to eminent consulting engineers they would have obtained—of course, for a large fee—the information which they only acquired at the expense of the contractors. As the position now stands, the firm who in the first case offered to supply plant of the type approved by the company's experts, will now have to face competition from all its competitors whose proposed systems of conversion have not been approved. This is not the only case in which the same procedure has been followed, as we know of one, for instance, at the present time in which, after tenders have been received on an exceedingly loose specification, new tenders are being asked for on the strength of the information obtained from the contractor who sent in the most complete information as to how the work in question should be carried out. In this latter instance, a consulting engineer's name appeared on the loose specification which first was issued, and we should think it would be only fair if he were made to pay the costs of all the manufacturing firms who really did his work for him.

Lightning Conductors.—In the matter of protecting overhead wires from lightning discharges, we in this country are much behind America and the Continent in experience. This is because the Board of Trade have objected to overhead power wires, and also because up to the present we have not the long overhead lines for conveying power in bulk at high voltages, which are becoming common in the countries above mentioned. An interesting editorial in the *Electrical World* of New York deals with the efficiency of lightning conductors. In this article it is pointed out that so long as the voltages were low, there was not much difficulty in protecting the machinery from lightning discharges. The question is raised as to whether the placing of the conductors underground is a sufficient protection against lightning in view of the fact that some submarine mines were exploded during the late war with Spain, although all the conductors leading to them were either underground or under water. The editor of our contemporary divides the lightning discharges into two kinds, the first of which is the direct stroke from discharge from the sky to earth, while the second is the induced discharge which always follows after the first discharge has taken place. The first of these is much less frequent than the others, but is apt to do much more damage. Again, the protection required varies with the class of electrical insulation involved. In a continuous-current system, by adding reactance in the circuit, one can protect against lightning, but of course such reactance can only be partly introduced into alternate-current circuits. Damage is very often done in these high-voltage lines, because after the discharge has once taken place the arc is maintained by the large power of the machines supplying the circuit. The question then comes to so set the spark-gaps that they are just sufficiently wide to hold up against the maximum working voltage, and that they will readily discharge in the event of the overhead wires being struck. On the other hand, if they are adjusted too accurately, a certain amount of resonance in the alternate-current machines and line is apt to cause interruption owing to the current leaping the spark-gap. The conclusion of the whole matter is that lightning protectors should be placed in extremely accessible positions where they can be easily inspected and cleaned, and the engineer in charge should experiment with the same in order to see exactly what is the best condition of the arrester in order that only lightning shall cause a discharge, and that this discharge shall take place before any damage can be done to the machines. The remaining problem of how to prevent the current from the machines maintaining the discharge when once started by the lightning is, in our contemporary's opinion, yet to be completely solved.

ROTHERHAM ELECTRICITY WORKS.

The ancient municipality of Rotherham successfully inaugurated its electricity supply on the 24th inst., when Councillor D. L. Winter, J.P., the chairman of the Electric Lighting and Tramways Committee, formally opened the new electricity supply works erected by the Corporation in Rawmarsh-road, and also set the generating plant in motion. The works have been erected according to the plans and specifications of Messrs. Kennedy and Jenkin. The total cost of the undertaking up to date has been about £224,500, though borrowing powers for £226,500 have been obtained. The site of the generating station buildings, being about 10 acres in extent, affords ample room for the extensions which may be found necessary at an early date, should the much-discussed subject of electric trams for the town and district be favourably settled.

The three-wire, low-tension system of supply has been adopted, with a pressure of 230 volts at the consumers' terminals. Plant has been put down sufficient to serve between 4,000 and 5,000 lamps at one time. The mains, however, are of sufficient capacity to serve 10,000 lamps at once. There are already about 2,000 or their equivalent connected up to the mains. The price to be charged for electricity per unit for lighting purposes is the moderate one of 5d. It may be mentioned in this connection that the gasworks are Corporation property, the price of gas being 2s. 4d. to 2s. 11d. per 1,000 cubic feet, according to the situation of the consumers' premises.

Before entering into a detailed description of the undertaking, it may be mentioned that the whole of the elo-

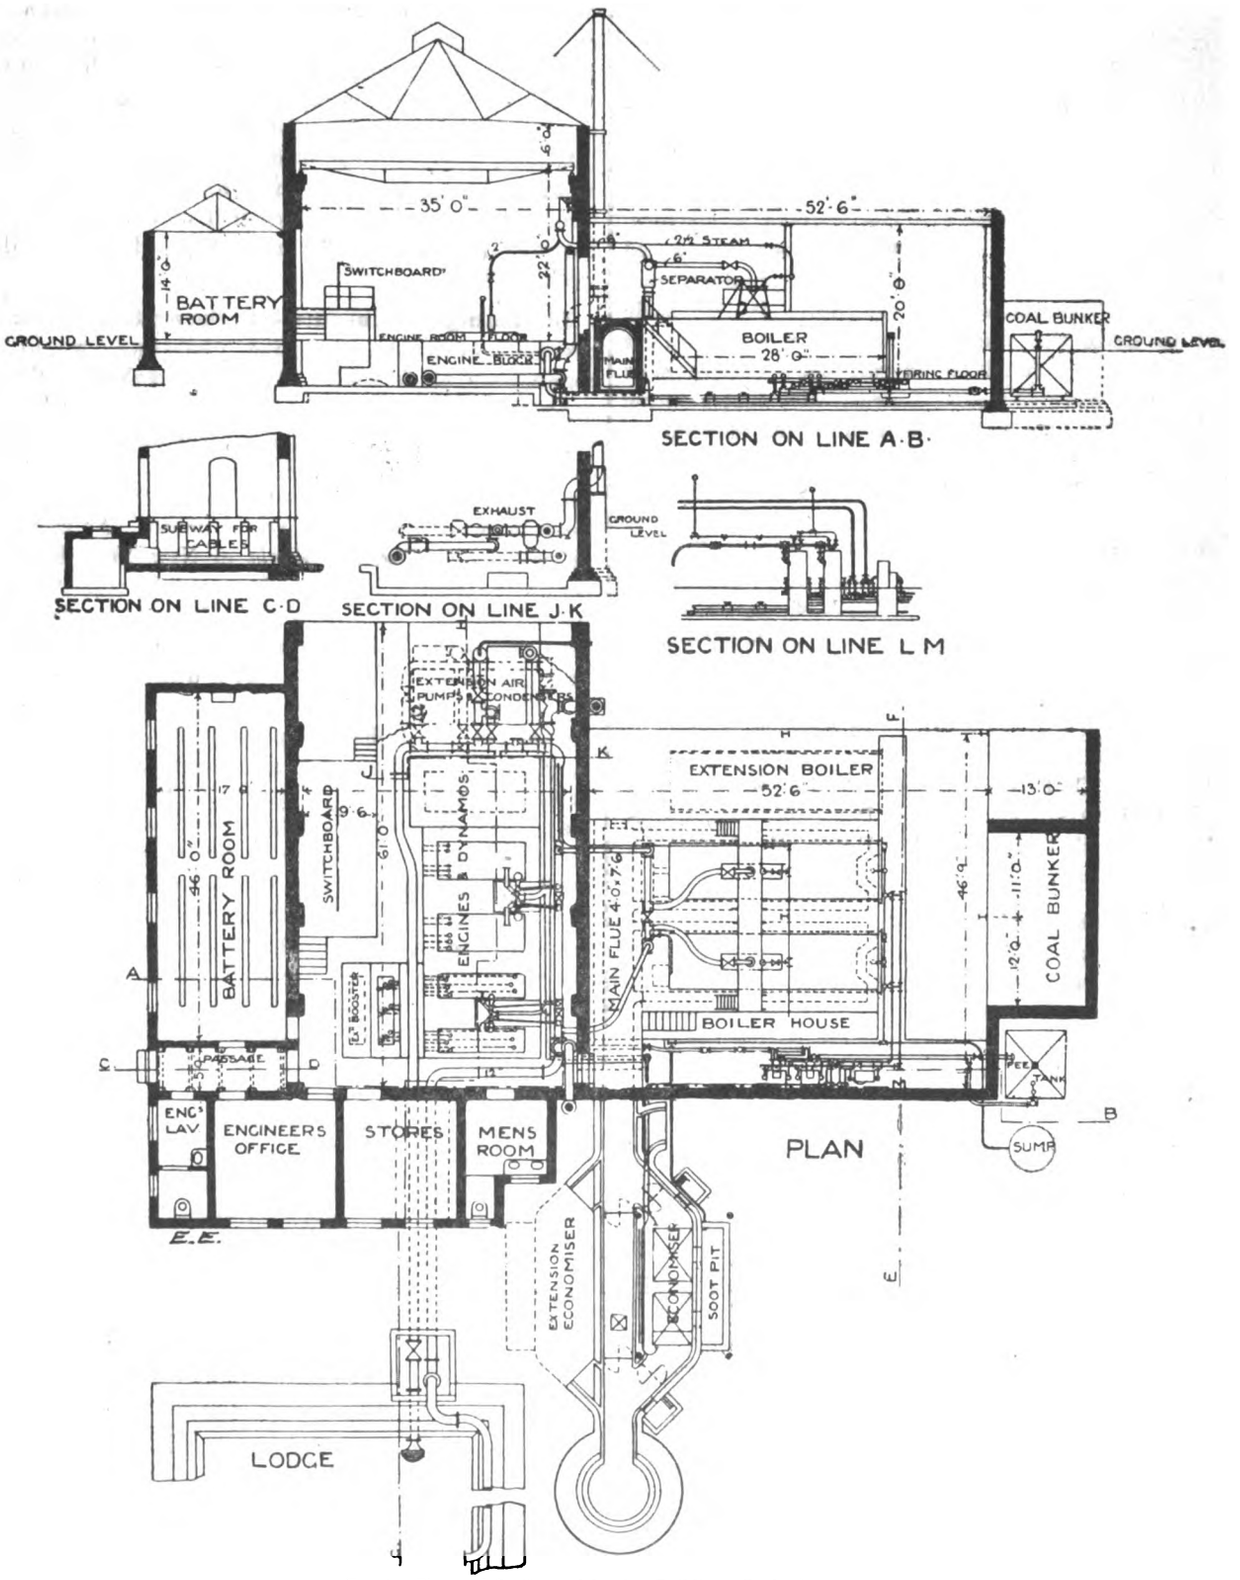

FIG. 1.—Plan and Sections of Station Buildings, Rotherham.

Digitized by Google

trical engineering work has been executed under the supervision of Mr. A. F. Davis, representing the consulting engineers. The resident engineer, to whose charge the works have now devolved, is Mr. Edward Cross. This gentleman commenced his electrical engineering experience in 1887 with the National Telephone Company at Whitehaven. His experience in lighting commenced in the year 1891 under the Preston Electric Supply Company, one of the

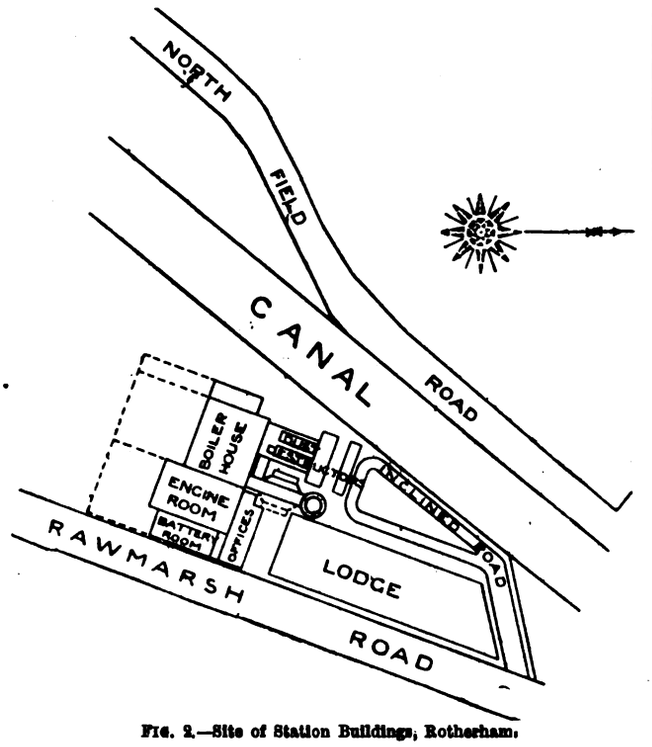

FIG. 2.—Site of Station Buildings, Rotherham.

oldest in the kingdom. With this firm he became acquainted with the change from the old overhead to the three-wire system now in use. Subsequently, under the Bradford Corporation as an engineer-in-charge of the lighting station, he conducted the conversion of the low-pressure three-wire system to the higher pressure, which is now commonly adopted by the large cities. At Bradford, too, he was engaged in the new large generating station for combined lighting and traction work, and after four years' service in that city he removed to Aberdeen, where, as chief assistant, he worked with the combined systems. Before Mr. Cross left that city the resources of their plant were increased from 1,100 i.h.p. to 2,700 i.h.p. In February of this year Mr. Cross received his appointment under the Rotherham Corporation.

We may now proceed to describe the works. The buildings, which were commenced in May, 1900, are of a substantial character, and comprise boiler-house, engine-room, battery-room, engineer's offices, storeroom, workmen's messroom, and water lodge. Their general arrangement will be seen on referring to Fig. 1, while Fig. 2 shows the position of the site and also the position of the refuse destructor, which it is proposed to ultimately combine with the scheme. Close to the chimney shaft, which is 160ft. high, is situated a large cooling pond for receiving the condensed steam from the engines and storage purposes. The boiler-house (see Fig. 1) contains at present two boilers of the Lancashire type, supplied by Messrs. Tetlow Bros., Hollinwood. They have shells 28ft. long by 8ft. in diameter, butt-jointed longitudinally and riveted with six rows of rivets. The furnaces and flues are 3ft. 3in. diameter, each consisting of 14 solid-welded steel rings united to each other by flanged seams with strengthening rings between. There are four conical cross tubes welded in each flue. Each boiler is fitted with a horizontal steam receiver measuring 8ft. long by 2ft. diameter. These receivers are attached to the boilers by solid-forged wrought-steel necks. The boilers are hand-fired, and have two lengths of firebars in each furnace, each length being 2ft. 9in. The working pressure is 160lb. per square inch. Hopkinson's fittings are used. With regard to the arrangement of the steam and exhaust piping, this is sufficiently clear in Fig. 1 as to make further description unnecessary. A Green's economiser is fixed, as shown.

In the engine-room (see Fig. 1) there are at present installed two large and two small sets of engines and dynamos, all of which plant, together with the condensers, which will be described later on, was supplied by Messrs. W. H. Allen, Son, and Co., Limited, Bedford. The engines are of the enclosed high-speed compound type, having two cranks at 180deg. actuated by two cylinders—one high-pressure and one low-pressure. The larger engines are each capable of developing 180 i.h.p. when running at a speed of 400 revolutions per minute, the steam pressure being 150lb. on the square inch. The high-pressure cylinder has a diameter of 11in. and the low-pressure cylinder a diameter of 19in., the stroke in each case being 8in. The cylinders are cast separately, and each cylinder is fitted with one piston valve. All the ports

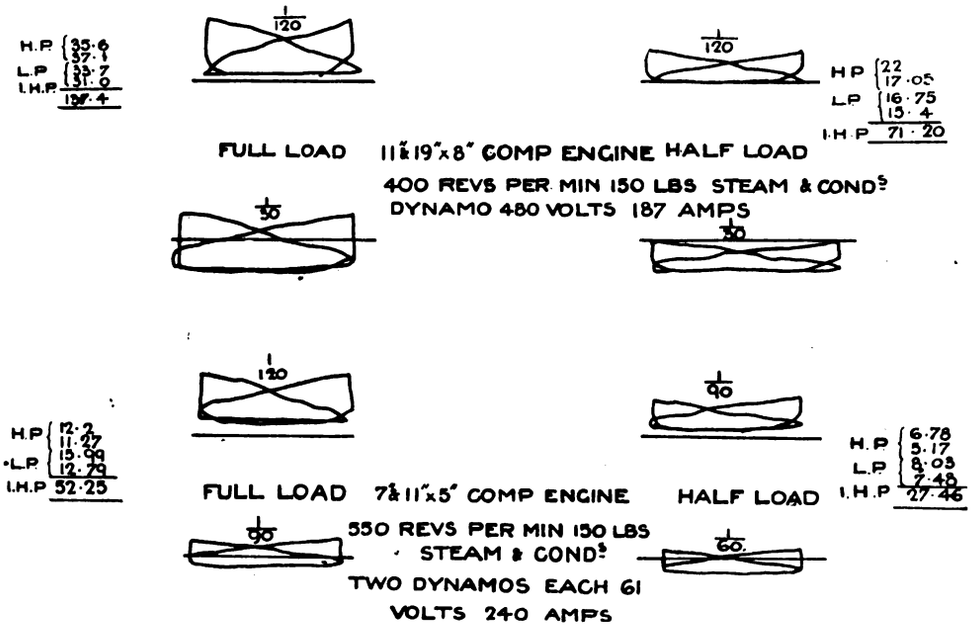

FIG. 3.—Indicator Diagrams taken from Large and Small Engines, Rotherham.

in the cylinder are made straight, so as to be as short as possible and self-draining. The cylinders are mounted on a cast-iron trunk, having a special arrangement of bush in the bottom of the distance piece by which the water is prevented from finding its way into the trunk. The trunk is fitted with two hinged doors at the front. This point is one of some importance, as one of the most usual complaints against engines having closed working parts is that of the trouble of opening the bolted doors. The working

Digitized by Google

parts are then easily accessible. The whole of the working parts are made of Siemens-Martin steel, and the pins for the cross-heads of a special hard and tough steel. The eccentric sheaves are forged solid with the shaft and have straps of cast steel. All the bearing surfaces are unusually large in order to ensure that the engine will run steadily, and without giving trouble at all speeds and loads. The crankshaft is 4½in. in diameter. An additional large bearing is provided at the flywheel end of the shaft to carry the weight of the armature without any appreciable amount of wear, so that the armature can be kept truly central with regard to its field. The main bearings and big ends are all lined with white metal, the shells of the bottom half main bearings being made of cast iron and the caps of steel. The engine is fitted with a system of forced lubrication, the oil being forced to all the working parts by means of a special valveless oil-pump worked from one of the eccentrics under an average pressure of about 25lb. per square inch. The result is that the mechanical efficiency of the engine is very high, being about 92 per cent. The governor is capable of being regulated by hand when running so as to give a variation of 5 per cent. in speed above or below the normal. Some of the indicator diagrams taken from both the large and small engines are shown in Fig. 3, while Fig. 4 gives the efficiency curves for one of the larger sets.

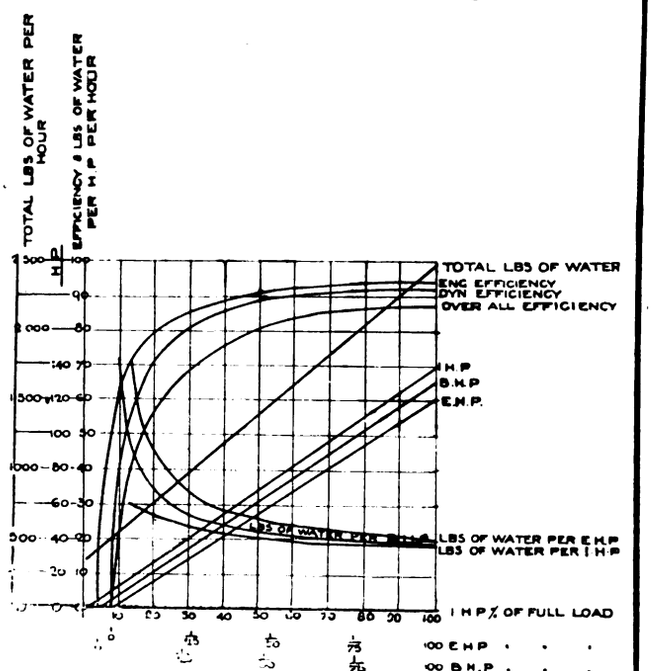

Fig. 4.—Efficiency Curves for one of the Larger Generating Sets, Rotherham.

The dynamos for the larger sets are capable of giving an output of 90 kw. each at full load, and are direct coupled to the engines. They are of the four-pole type, with barrel-wound armatures, and have four sets of carbon brushes. The loops of the barrel winding are formed in one place on special shapers, and are connected up in due order by the commutator lugs. The field-magnet winding is compound, the shunt being arranged to give an E.M.F. from 460 to 520 volts when working as a shunt machine, while the series winding raises the volts from 500 at no load to 550 at full load when required for traction load. A special regulator, designed in principle by Messrs. Kennedy and Jenkin, is placed in the circuit of the series winding, so that when the two larger machines are worked in parallel, the compounding effect of the series turns may be altered without affecting the equal division of the current between the dynamos. This is secured by a switch which, in proportion as the current is diverted from the series winding, inserts an equivalent resistance, so that the total resistance of the main lead to the switchboard is unaltered. The efficiency of the dynamo is as follows: full load, 92·4 per cent.; three-quarter load, 91·7; half-load, 90; quarter load, 83·7; one-eighth load, 72·6. The arrangement of the series regulator is shown in Fig. 5. The above plant is capable of developing an overload of 20 per cent., with a maximum boiler pressure of 180lb. on the square inch, non-condensing. Each of the two smaller sets consist of one engine and two dynamos, the engine being similar in construction to the larger sets, and having high-pressure cylinder 7in. diameter and the low-pressure cylinder 11in. diameter, the stroke in each case being 5in. The engine runs at a speed of 550 revolutions per minute. The two dynamos have a combined output of 29 kw., and are coupled one on either side of the engine. They are of a similar construction to the larger sets, and are of the two-pole inverted horseshoe type, with drum-wound bar armatures, and can be run as balancers on the three-wire system. The brushes in this case are of copper gauze, and are arranged on the horizontal diameter of the commutator. The engine-room plant also comprises two motor-driven boosters mounted on a common shaft. These were supplied by Messrs. Thomas Parker, Limited.

The condensing plant consists of a condenser, air-pump, and circulating pump, and is driven by a compound engine. The condenser has a surface of 1,000 square feet. The casing is of cast iron, cylindrical in form, fitted with suitable branches to take the main exhaust, air-pump suction, and circulating water inlet and outlet. The tube plates are of the best rolled brass, 1in. thick, and all the tubes are of solid-drawn brass, ⅝in. external diameter by 18 B.W.G. thick. The tubes are fixed in the tube plates by means of screwed ferrules and tape packing, and the ferrules are provided with lips to prevent the tubes from slipping out of place. One of the water heads of the condenser is divided by a diaphragm, so that the water will first pass through the lower half of the tubes and thence through the upper half to the discharge outlet at the top of the condenser. The air-pump is of the Edwards single-

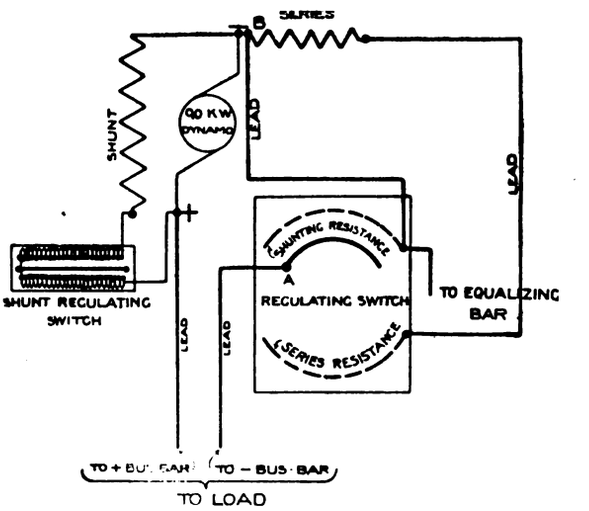

Fig. 5.—Arrangement of Series Regulator, Rotherham.

acting vertical type, having a diameter of 20in. by 11in. stroke. The outer casing of the pump is of cast iron, and the working barrel, valve seatings, and guards of gunmetal. The bucket rod is of bronze, and the valves are of the best rolled brass. The pump is capable of dealing with 12,000lb. of exhaust steam per hour. The circulating pump is of the double-acting type, having a diameter of 15in. by 11in. stroke. The outer casing of the pump is of cast iron, the working barrel and valve seatings of gunmetal, and the suction and delivery valves are of best vulcanised rubber with gunmetal guards. Both the air and circulating pumps are driven direct by means of side rods by one compound engine, having cylinders 9in. and 15in. diameter by 11in. stroke. A crankshaft, flywheel, and governor—of the "Pickering" type—are provided to ensure steady running. All the working parts are of Siemens-Martin steel, and have a tensile strength of 28 to 32 tons per square inch, with an elongation of 28 per cent. in 2in.

The equipment of the battery-room consists of 256 K.W.T. type cells manufactured by the Electrical Power Storage Company, Limited, the battery being capable of maintaining a discharge of 50 amperes for five hours, or 75 amperes for three hours, or 100 amperes for 30 minutes. The containing boxes are of glass, and each cell contains 15 plates, separated by glass tubes held in position at the top and bottom. The cells are erected on two-tier stands, with iron

Digitized by Google

standards and wood bearers. The approximate weight of each cell complete, with acid, is 240lb.

Coming now to the main switchboard, this is of the usual type specified by Messrs. Kennedy and Jenkin for three-wire systems. The board is mounted on a platform raised about 3ft. from the floor level, and has been supplied and equipped by Messrs. Kelvin and James White, Limited, of Glasgow and London. It consists of enamelled slate slabs mounted on a steel framework neatly faced on the front and edges with a polished teak moulding, and an electrically-driven clock of this firm's make is fitted at the centre. The total length of this switchboard is 16ft. 6in., and it is divided into 11 separate panels, three of which are at present filled in with roughened glass, as it is intended at a later date to fit the apparatus required for traction purposes on these panels. Each panel contains both the positive and negative switching apparatus for the machines and feeders, as well as the plugging bars for connecting the dynamos or batteries to the 'bus bars and from the 'bus bars to the feeders. The two upper panels to the right contain all the instruments and switch gear for the two large dynamos, and space is left at the top for the addition at a later date of two lighting feeders. The next panel in order contains all the voltmeters and voltmeter switches, as well as the earthing and middle-wire ammeters. The panel at the extreme left contains all the apparatus for the batteries and motor-driven boosters. The other two panels contain all the apparatus for the two balancing dynamo sets, as well as two feeders. The switchboard as at present arranged is capable of dealing with two 500-volt dynamos, four balancing 250-volt dynamos, two three-wire feeders, as well as two boosters and two batteries. As mentioned above, however, space is provided by which instruments and switch gear for two other three-wire feeders, and the traction apparatus for the two large dynamos, can be fitted. All the ampere gauges on the board are of the Kelvin sector or edgewise pattern, the voltmeters are of the Kelvin S.R. (siphon recorder) pattern, and in the earth circuit there is fitted a Kelvin recording ammeter and short-circuiting switch. The automatic cut-outs fitted in the dynamo and steam balancing sets are double-pole, and are of the Ferguson and White's patent type, being arranged to work either as a maximum-current cut-out or a minimum-current cut-out. During working it is set as the former, and when it is desired to shut down a machine it is changed to act as a reverse-current cut-out. This change is made by turning over a small key from position marked "maximum" to "minimum." By the

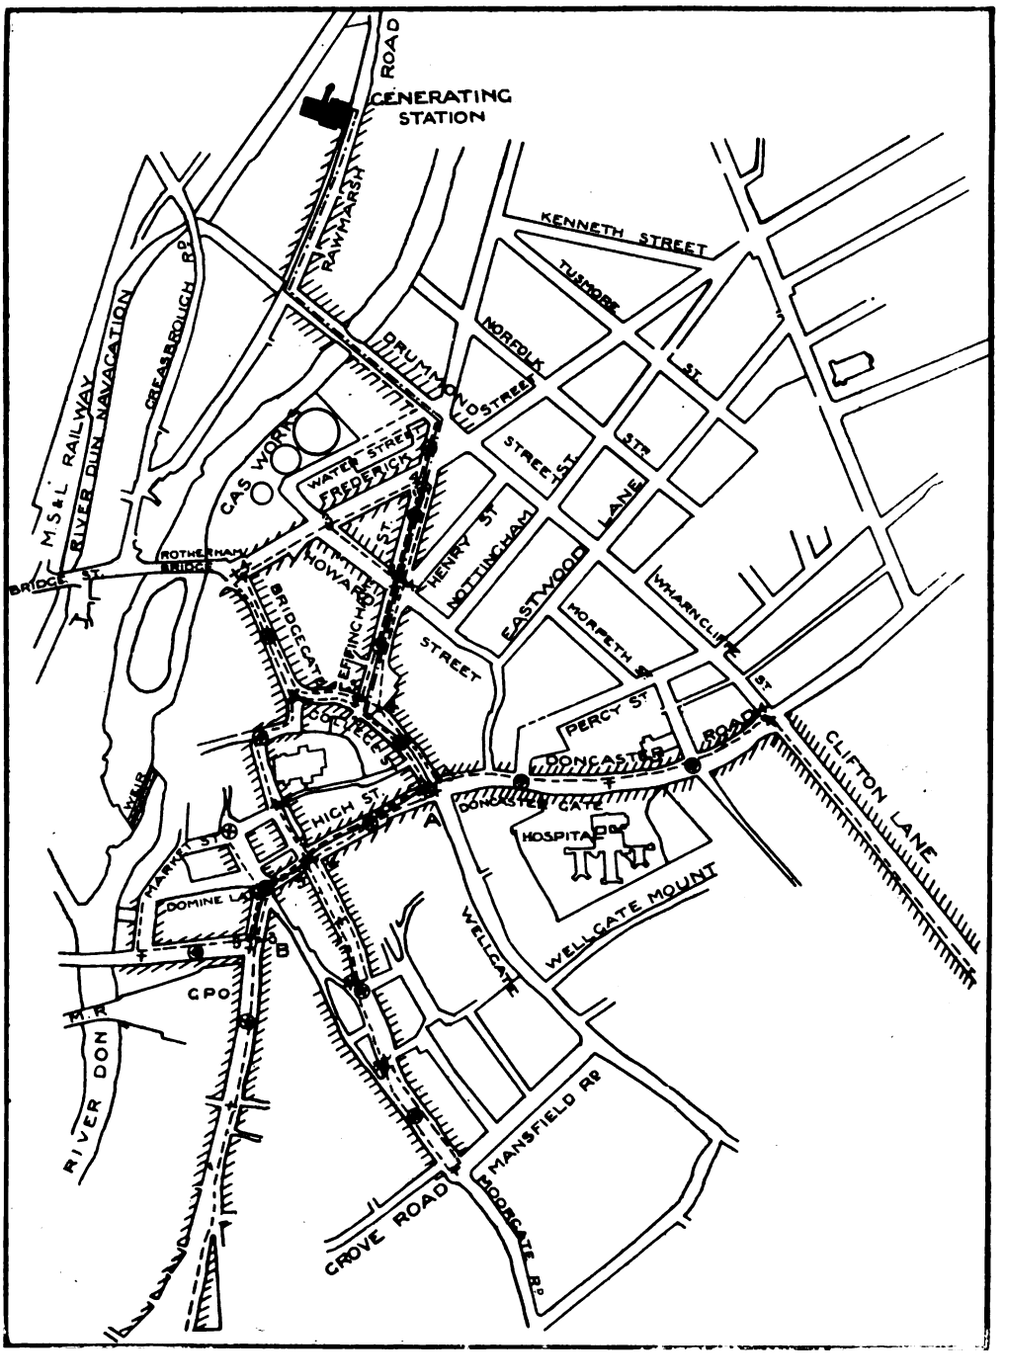

Fig. 6.—Map of Mains, Rotherham, showing Feeders marked ——; Distributors — — — Feeding Points •; Proposed All-Night Arcs ⊹ and Half-Night Arcs (+).

Digitized by Google

adoption of this type of cut-out it is impossible to hold the switch closed should an excess current be passing, and the same handle is arranged so that it can be used as an ordinary switch. Carbon breaks and asbestos screens are provided for taking and effectively wiping out any spark that may occur. In conjunction with the booster, a reversing switch is fitted, which is interlocked with the battery regulating switch so that it is impossible to move the former, except when the latter is in one of two equivalent positions in which the whole of the cells are in circuit. The booster can then be used either to charge the battery or to assist in the discharge. Two sets of 'bus bars are provided at the back of the board, and consist of bare copper bars supported on insulators, which are fitted to a steel frame fixed to the framework of the board. The shunt regulating switches for the dynamos, batteries, and boosters are mounted on the handrail, and are of the rectangular sliding pattern, the leads from these being carried down the pillars supporting the handrail to the resistances fitted in the trench below the switchboard. Ferranti meters are fitted in the dynamo and balancer circuits, and Chamberlain and Hookham meters are fitted in the battery circuits. Two of the latter instruments are provided for each battery, one of them registering charge and the other discharge, and arrangements are provided in these meters so that, although both of them are always in circuit, only one of them will read, depending on the direction of the current.

With regard to the outside work, the contract for the supply and laying complete of the mains in connection with this station was placed in the hands of Callender's Cable and Construction Company, who have also excavated the trenches and done all roadway work in the borough. The cables are concentric and triple-concentric, and are of Callender's vulcanised-bitumen sheathed type. They are laid on the solid system in a wooden trough run in with Trinidad bitumen, the main thus made being protected by a tile cover. Starting from the generating station, two ·3 concentric cables are laid as feeders. Three-core pilot wires are laid along with these cables, and there is also a neuter wire, consisting of a single-conductor ·1 cable, which extends from the generating station to the network, where it is connected with the middle wire at a special neuter box. The lengths of the feeders are respectively 1,040 and 780 yards. Each feeder supplies its own network, but the two networks are interconnected by means of dividing-up boxes which are placed on the run of the distributors in special pits by themselves. If necessary, therefore, either feeder can be cut out and the entire network supplied by the other. Spare ways have been provided along the line of the feeders to be available for further extensions. These consist of stoneware conduits made by the Albion Clay Company, and terminate in the centre of the town. The distribution network consists throughout of triple-concentric cable, having a sectional area of ·10, ·10, ·05 square inch. These distributors are laid in a trough separate from the feeders, and are also on the solid system. Arc light cables have been provided, and are generally laid along with the distributors. These cables are provided in view of future contingencies, although for the present it is not intended to deal with any arc lighting in the borough. Fig. 6 shows the positions of the feeders and distributors, and also of the proposed arcs. The whole of the main work was carried out by Mr. W. C. Knight, who acts as the Callender Company's resident engineer in the district.

It will be gathered from the above that Rotherham has come into possession of a thoroughly well designed and equipped electricity works, and one, therefore, which may be reasonably expected to render a good account of itself. For our part we wish the undertaking every success.

ILFORD INAUGURAL CEREMONY.

At the invitation of the Urban District Council, a large number of ladies and gentlemen assembled in the parochial hall on Saturday afternoon to witness the ceremony of the inauguration of Ilford's electricity supply undertaking. The chairman (Councillor B. Bailey) presided, and was supported on the platform by Mr. L. Sinclair, M.P., Mr. W. C. C. Hawtayne (consulting engineer to the Council), Mr. A. H. Shaw (the resident electrical engineer), the Mayor of West Ham, the members of the Council, and others.

After the Chairman had described the undertaking and Mr. Hawtayne the works (a full description appeared in our last issue), Mr. L. Sinclair proposed a vote of thanks to the Electric Lighting Committee, and in doing so he expressed the opinion that the works had been constructed on the most economical basis. He complimented the committee on the excellent work they had carried out so successfully.

Other speeches followed, and then the chairman called upon Mrs. Henry Weeden, the wife of Councillor Weeden, a past chairman of the Electric Lighting Committee, to declare the works open and switch on the light. This pleasing formality over, Mrs. Weedon was presented with a handsome silver lamp fitted for the electric light, a gift which she gracefully acknowledged in a few well-chosen words. More speeches followed, and then an adjournment was made to an adjoining room, where several electrical firms are exhibiting this week. These firms include the Robertson Lamp Company, the General Electric Company, Messrs. Veritys, Limited, and the Magnet Electrical Engineering Company, with the usual show of heating and cooking apparatus, electric fans, telephones, motors, fittings, etc. A noticeable feature of the exhibition, which remains open till to-morrow evening, is an interesting demonstration of the manufacture of Robertson lamps by a glass-blower specially lent by the General Electric Company, Limited. The various processes of manufacture are shown in a popular manner, and should do much towards familiarising the Ilford public with the nature of the lamp.

In the evening a banquet in honour of the occasion was given by the Council at the Angel Hotel, at which some 70 gentlemen were present. An excellent dinner was served. After the loyal toasts,

Councillor HENRY WEEDEN proposed "Ilford's Electricity Undertaking." He emphasised the fact that it was the people's undertaking, and that the Council in deciding upon the work had pledged the credit of the town. The success of the undertaking depended upon the people themselves, and if they took up the electric light in the way the Council hoped they would, it would be possible in a very short time to give a supply at an infinitely cheaper rate than it was at present necessary to enforce. With regard to traction, it must be admitted that the Council had done wisely in securing the right to run tramways in the district. Trams would not only benefit the town enormously, but would develop the trade of the whole district. The Council intended to work them solely with the view of benefiting the community, and he hoped to see a tram service running within a very short time. In conclusion, Councillor Weeden acknowledged the good work done by Mr. Hawtayne in his capacity as consulting engineer to the Council.

The CHAIRMAN (Mr. B. Bailey), in reply, said they had embarked upon an undertaking which must prove of great value, not only to the town of Ilford, but to the district at large. In keeping the electrical undertaking to themselves on behalf of the ratepayers, the Council had stopped the financier from stepping in and taking money out of the town. A number of syndicates of financiers had approached the Council with a view to obtaining the powers conferred upon the Council, but the Council were not going to allow such vast and valuable undertakings as the electric light and the electric tramways to pass out of their hands. He had not the slightest fear whatever with regard to the future of Ilford's electrical undertaking.

Mr. SINCLAIR, M.P., in giving the "Engineers and Contractors," said municipal trading was always questionable when you could get companies to do the work. But for all that, it was the duty of a council to see that efficient light and tramway communication in the district was provided for the inhabitants. The concord which had existed throughout between the Council, the engineers, and the contractors was exceedingly gratifying, and when they saw

Digitized by Google

that they had pulled together with one object, giving the town as good a light and plant as science could produce, they were to be heartily congratulated.

Mr. G. SUTTON, of W. T. Henley's Telegraph Company, testified to the cordial relations between the Council, engineers, and contractors which had existed on all occasions. Referring to the question of a day load, he expressed the hope that the Council would offer cheaper rates for the supply of current for heating and cooking purposes.

Mr. HAWTAYNE also responded to the toast. He thought the ratepayers ought to be very thankful to the Council for having refused to lease their tramway undertaking to the syndicates which had come forward. There were as many as 130 tenders for the work which had just been completed, and he never wished to see a more responsible set of contractors than those who had carried out the work.

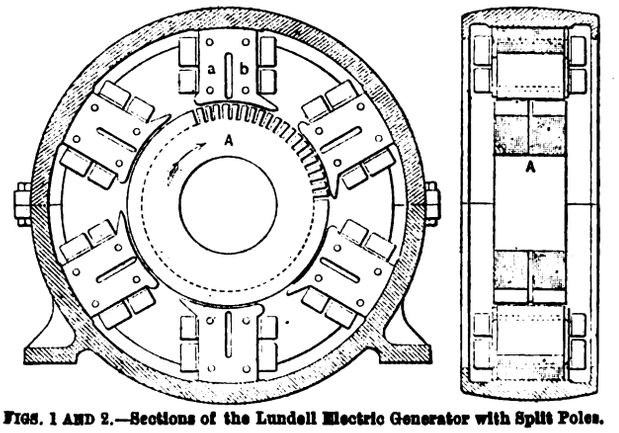
Mr. MAX BYNG and Mr. A. SHAW also acknowledged the toast in appropriate terms.

During the evening the CHAIRMAN called attention to the fact that the electric light had just been switched on in the streets for the first time with complete success—an announcement which was received with cheers. Of the success which is certain to attend the Council's venture we ourselves entertain not the slightest doubt, and it only remains for us to congratulate the town of Ilford on the expedition with which the terms of the provisional order have been fulfilled.

MESSRS. J. H. HOLMES AND CO.'S WORKS.

We recently had the opportunity of paying a visit to the works of Messrs. J. H. Holmes and Co., at Newcastle-on-Tyne, in order to witness a trial of two 150-kw. direct-current dynamos of the Lundell type, which that firm are now manufacturing in large numbers in this country. At the same time, through the kindness of Mr. J. H. Holmes, we had an opportunity of inspecting again the whole of the works and of seeing the improvements which have been made in the equipment of the same by the use of electric motors for driving isolated tools in positions in which they could not be placed unless they were so driven. The economy obtained in this way in the floor space of the works, as compared with the quantity of work which can be turned out, is most remarkable. We propose, however, to deal first with the description of the two large dynamos we saw under test.

As some of our readers may not be conversant with the details which distinguish the Lundell type direct-current dynamo from other multipolar machines, we propose to give a brief *résumé* of the essential features of the same. These



FIGS. 1 AND 2.—Sections of the Lundell Electric Generator with Split Poles.

are shown in Figs. 1 and 2. The great feature in this electric generator, apart from the well-balanced design, is the split pole-piece, the object of which has been previously explained by us, but which will bear repetition. Thus, when the armature of a dynamo is run in the direction indicated in Fig. 1, the armature currents tend to weaken the field strength under the edge of the pole-face which the conductors approach. This weakening results in a shifting of the neutral axis and also of the axis of commutation. Mr. Lundell prevents this weakening of the induction by imposing a reluctance in the path of the cross field. He also ensures by the design that the action of the compound winding shall tend to slightly increase the induction at the point where it is useful for commutation. Thus the half of the pole marked (*b*) in the figures has a large pole-shoe, which reduces the air-gap reluctance, and results in the iron of (*b*) being strongly saturated when the half of the pole marked (*a*) is still magnetised considerably below the

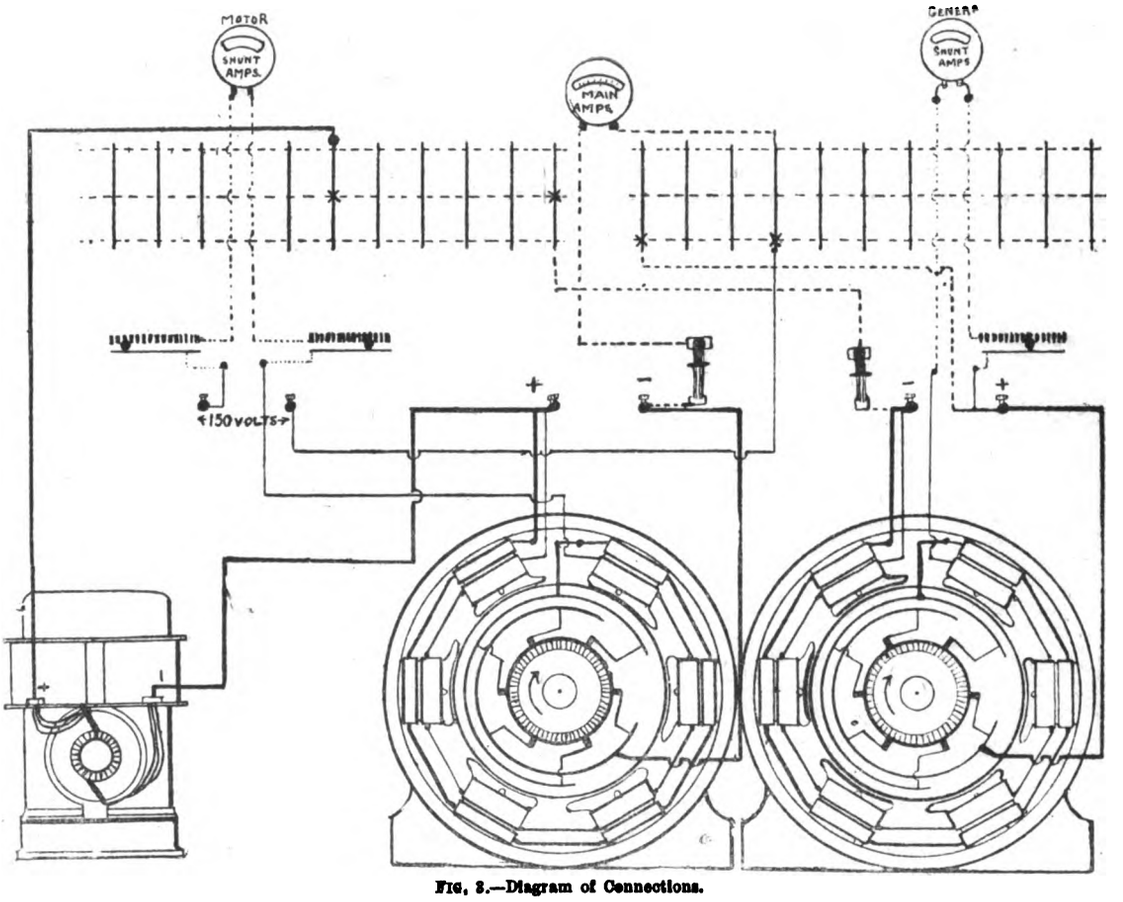


FIG. 3.—Diagram of Connections.

Digitized by Google

saturation point. Any increase in the magnetising force consequently increases the induction through (*b*) but slightly, but greatly strengthens the induction through (*a*), and hence keeps up the commutating field.

From actual curves obtained on these machines, it is proved that by careful design the induction at this point can be kept either absolutely constant for all loads, or can be actually increased if it is found necessary to do so. The split pole also halves at least the cross-magnetising effect of the armature current on the induction issuing from any one pole. The two machines of which we witnessed the tests are designed for coupling to high-speed engines running at 300 revolutions per minute. As the engines were not at the works, the tests were carried out on the Hopkinson principle, the diagrams of connections being as shown in Fig. 3. From this it will be seen that the two machines are connected in series, and in series with them again was connected a smaller generator which added sufficient energy to keep the two machines going with their normal current and practically full voltage. The field strength was so far varied that the one machine acted as a motor while the other acted as a generator. It was found that the series connection gave more stability in running than if the two machines were connected in parallel, and current added from an external source. As will be seen from the connections in the diagrams, the smaller dynamo supplying the excess energy had to be able to take the field current of the machines while giving comparatively low voltage. Each of the dynamos under test was designed to work at any voltage from 240 to 275, the current varying from 625 to 687 amperes. The normal speed of the machines was 300 revolutions per minute. Again, while the normal output of the dynamo was 150 kw., it was specified to stand 165 kw. for at least two hours. The normal load trial was made for 10 hours. The machines in question are somewhat of the style shown in Fig. 4, which is a photograph of a somewhat smaller set. The winding of

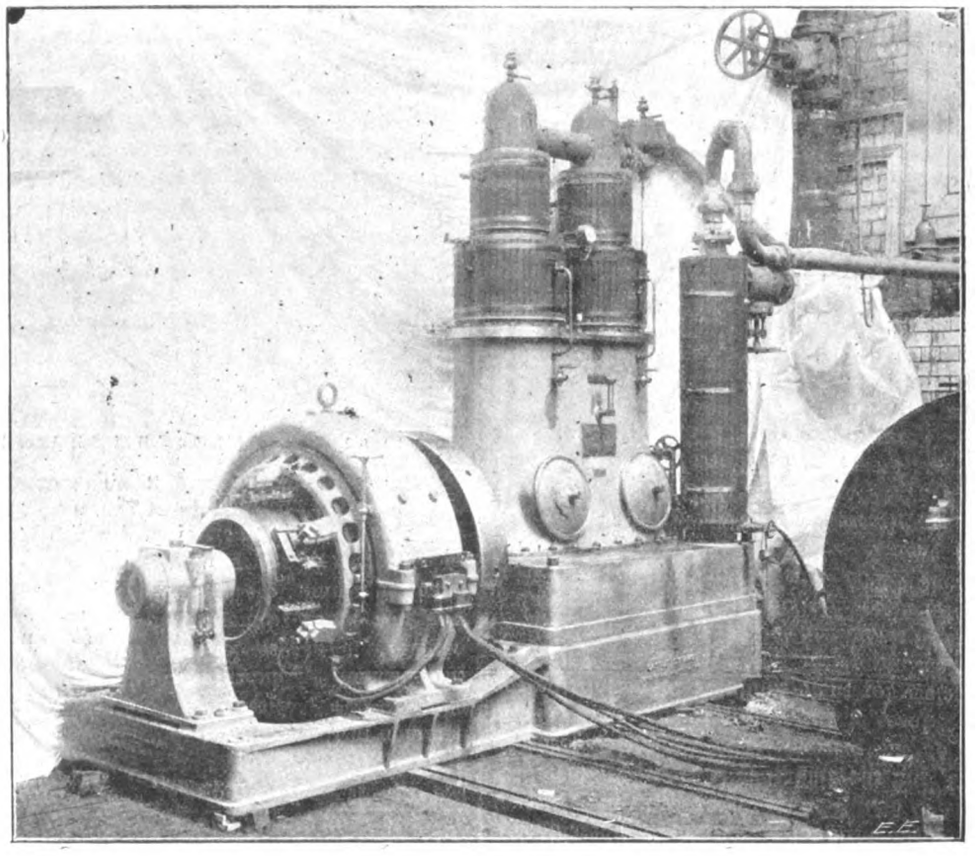

FIG. 4.—View of Lundell Generator, manufactured by Messrs. J. H. Holmes and Co., and coupled to a Willans Engine.

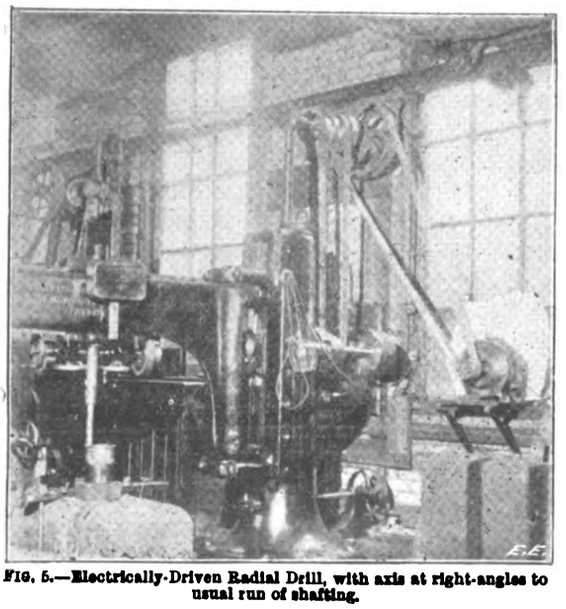

FIG. 5.—Electrically-Driven Radial Drill, with axis at right-angles to usual run of shafting.

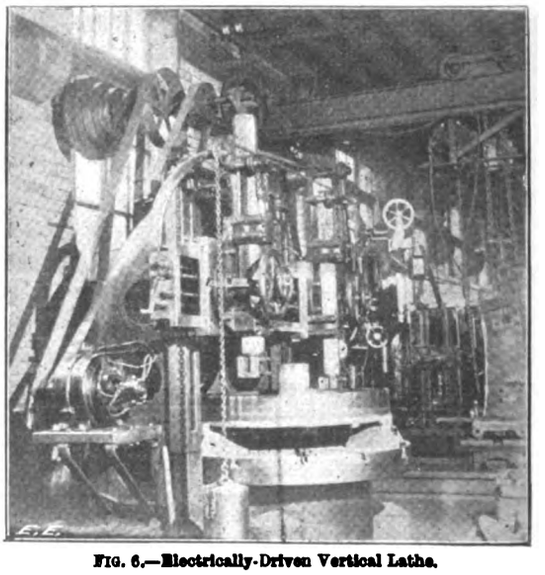

FIG. 6.—Electrically-Driven Vertical Lathe.

Digitized by Google

the field magnets is done by a combination of shunt and series coils, there being nine series turns on each pair of poles. This raises the vexed question as to whether there are 4½ turns on each pole or five turns on the one and four on the other. These series turns have a considerable advantage with the Lundell construction, in that the extra excitation as the load increases tends to

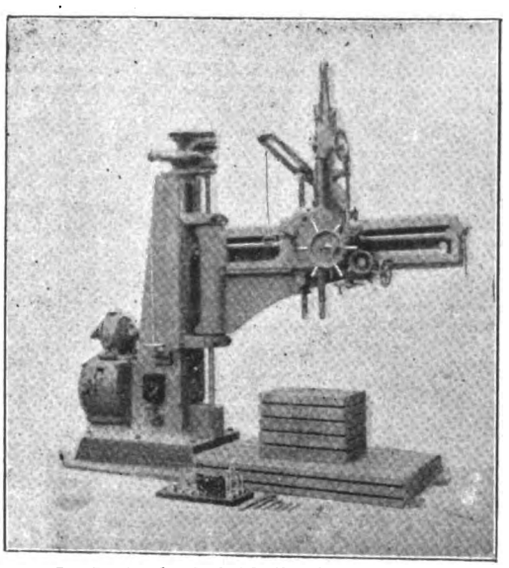

FIG. 7.—Another Radial Drill with Geared Motor.

keep the commutating field absolutely constant. The results obtained on the 10 hours' trial are given in the accompanying table. After this 10 hours' run the following temperatures were taken on the various parts of the machine: Thus, on the machine acting as the motor, the temperature of the armature was such that the increase over the temperature of the air was only 36deg. The temperature rises on the other parts were as follows: armature conductors, 46deg.; pole.tips, 36deg.; armature core (teeth), 44deg.; and the armature spider, 31deg. As the motor was really working at more than normal load, these rises are appreciably more than were found for the

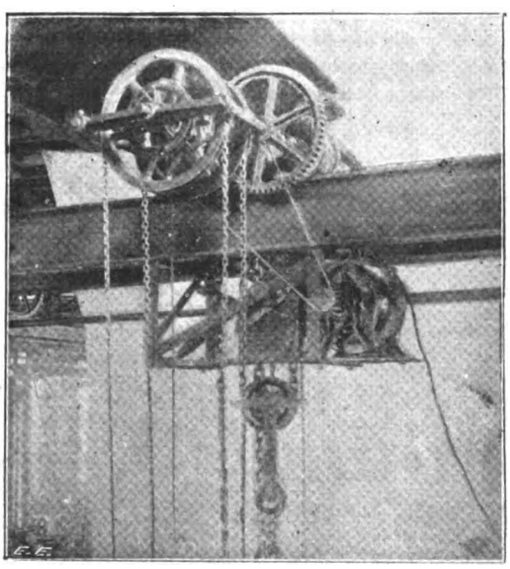

FIG. 8.—Motor with Chain Drive to Crane.

other machine acting as the generator. In this the following were the temperature rises: commutator, 32deg.; armature conductors, 38deg.; pole-tips, 31deg.; the projecting core teeth of the armature, 40deg.; and the armature spider, 23deg. On the day the tests were made the temperature of the atmosphere was about 65deg. F. These abnormally low temperature rises show that the machines are well within their rated output. Another test applied was to see how far the brushes could be moved round the armature at full load without causing sparking. This we found to be no less than 2½in. on a commutator 2ft. 4in. in diameter. From this we are sure that the brushes of the machine could be kept fixed for all loads without any sparking occurring. As, however, the machines were not connected directly to any prime mover, a direct observation on this point could not be made. But the tests we applied showed how well the Lundell split pole is capable of overcoming the distorting effects of armaturing action on the field magnet. As regards

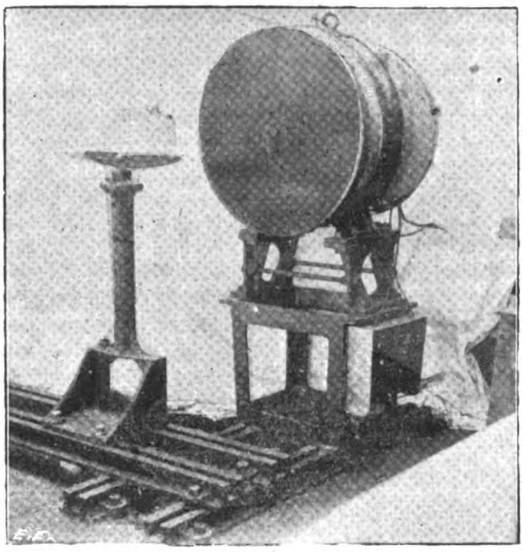

FIG [9.—Motor acting as a Face-Plate Lathe.

the overall efficiency of these machines, this can be readily ascertained from the figures given in the table.

As the current is constant, one only needs to take the ratio of the voltages of the generator to that of the motor. For instance, in the present case, assuming that the average voltage of the generator was about 241, and that of the motor 293, the overall efficiency of the two sets is 241 ÷ 293, or 82½ per cent. This brings the overall efficiency of each machine to about 91 per cent. It must be remembered that when making the tests the machines were coupled up temporarily and run in bearings which were by no means rigid, which would certainly increase the frictional losses. The results obtained, therefore, are exceptionally good. The following are the weights of the various parts of these dynamos:

	t.	cwt.	qr.	lb.
Field, complete	3	4	1	0
Armature, complete	2	12	0	0
Bearing bracket	0	10	0	14
Brush gear	0	6	1	8
Bedplate for two dynamos	2	11	0	0
Spindle (included in armature weight given above)	0	17	0	0
Total of two machines, complete on bedplate	15	17	0	0

Coming now to the descriptions of the mechanisms used

Digitized by Google

in various parts of the shop for driving tools, it is well to mention, in the first place, that in the heavy machine shop most of the tools are placed in one bay, while the next bay parallel with it was formerly used as an erecting shop. The pitch of this was not sufficient to allow of the erection of countershafting under the rails of the travelling crane. It meant, therefore, that the erecting shop could not well be used for machine tools until some method of motor driving had been devised. This can be seen well from Fig. 5, which is of a radial drill. The rail seen just over the top of the drilling machine carries the travelling crane, and shows what little headroom is left. In the case of this radial drill, the motor, which is of the Lundell type, is carried on a small bracket from the wall, and drives the tool by means of a belt. Somewhat the same method of driving is used for the vertical lathe (seen in Fig. 6), except that the motor is carried from a small bracket on the machine itself in order that the machines may be set back close to the wall. Each of these tools is placed near the wall of the erecting shop, leaving ample space in front of them for the normal work of the department.

Another and, perhaps, more compact way of connecting the motor on to a radial drill is shown in Fig. 7, in which the use of belts is dispensed with. In this case the motor drives by means of a Hans Renold chain the main shaft of the radial drill. This use of a bicycle chain has also been employed in the overhead crane in this erecting shop, which is shown in Fig. 8. This has proved to be of very great service. The motor is carried on the under side of the crane girders, and is switched on and off by cords from the floor level. Where considerable lifts have to be made, as is the case in these works, in getting material raised and lowered from one floor to another, the quick speed which is obtained by the motor drive results in a very great saving of time. In the pattern-making and carpentering department of the works—of which we regret we have not more photographs—almost all the motors are carried on the underside of the floor. The space so occupied near the ceiling in a store is of exceedingly little value, whereas the space that the motor otherwise would require on the floor of the pattern-making department is exceedingly valuable. These motors are, in most cases, hung on a hinged frame, so that the weight of the motor is used to give the required tension in the belt. This is adjusted by means of a counter-weight, also connected with hinged framework, the result being that a very steady drive is obtained which is quite independent of the stretching of the driving band. Fig. 9 is a view of another ingenious device which was rigged up temporarily in time of emergency, but which, in consequence of the good work it has done, has remained a permanent tool in this wood-working department. It consists of an electric motor with especially heavy and coned bearings, to which an iron face plate is attached. The motor drive on this face plate is, of course, quite positive, and it has been found to be of very great service when turning woodwork of large diameter. The power for driving these motors and for the supply of the energy required in the testroom is obtained from a central station in the works themselves.

THE COMING VISIT OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO BERLIN.

The Cable Works of the Allgemeine Elektricitats-Gesellschaft

(Concluded from page 750.)

Cables for submarine telegraph purposes are not lead-covered, as the weight has to be kept as small as possible in consideration of the great lengths used. They can be made by the Allgemeine Elektricitäts-Gesellschaft up to lengths of 6,000 km. without jointing. Guttapercha is used as the insulating material, being pressed round the core in several jointless covers. This material possesses high insulating properties, and is not affected by salt water. Over the guttapercha several layers of impregnated jute string are wound, and over this again an armouring of steel wire—light for deep-sea cables, and heavy for shore cables to protect it against ships, anchors, etc.

The displacement of bare overhead telephone cables by underground cables with insulated lead and return, which is rapidly taking place in towns, has given rise to a large demand for lead-sheathed cables made up of many pairs of wires. The Allgemeine Elektricitäts-Gesellschaft have laid down special machinery to meet with this demand, and manufacture telephone cables containing as many as 250 pairs. Each pair consists of one tinned and one untinned wire. The separate wires are loosely insulated with paper, so as to allow a free passage of air from end to end. This air insulation is of great importance, as experience has shown that the better the ventilation the lower the capacity of the cables, and the better their speaking properties. Telephone cables which are laid directly in the ground are generally further protected by the addition of an armouring of wire, trapezoidal in section. Cables which are to be laid in conduits are not armoured, but the lead covering contains an admixture of tin.

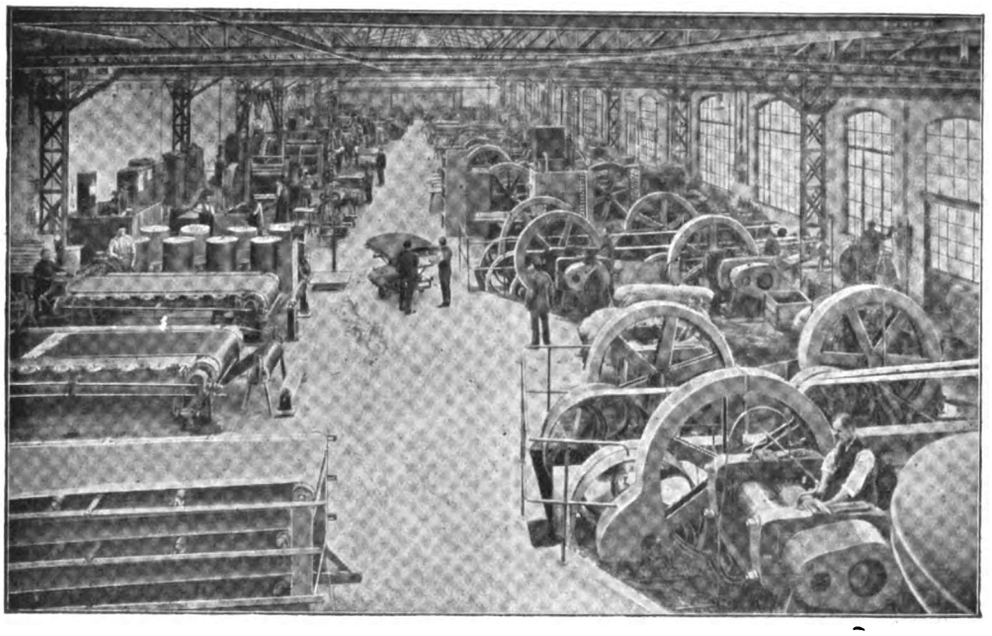

FIG. 5.—Insulation Kneading Mills, Oberschoneweide.

Besides the manufacture of cables, the Allgemeine Elektricitäts-Gesellschaft have specially-equipped departments for the manufacture of all kinds of wires, cotton and silk covered. The insulation of these is either a simple lapping of cotton or silk or jute, or a braiding, or a combination of lapping and braiding. There is a large demand for wires for damp or wet situations. The first class, those for damp places, are covered with cotton, then pure Para rubber, then another covering of cotton, and then braided over all. This class of wire is extensively used for the exposed system of wiring rooms, etc., with insulators, so much in vogue on the Continent. For wet

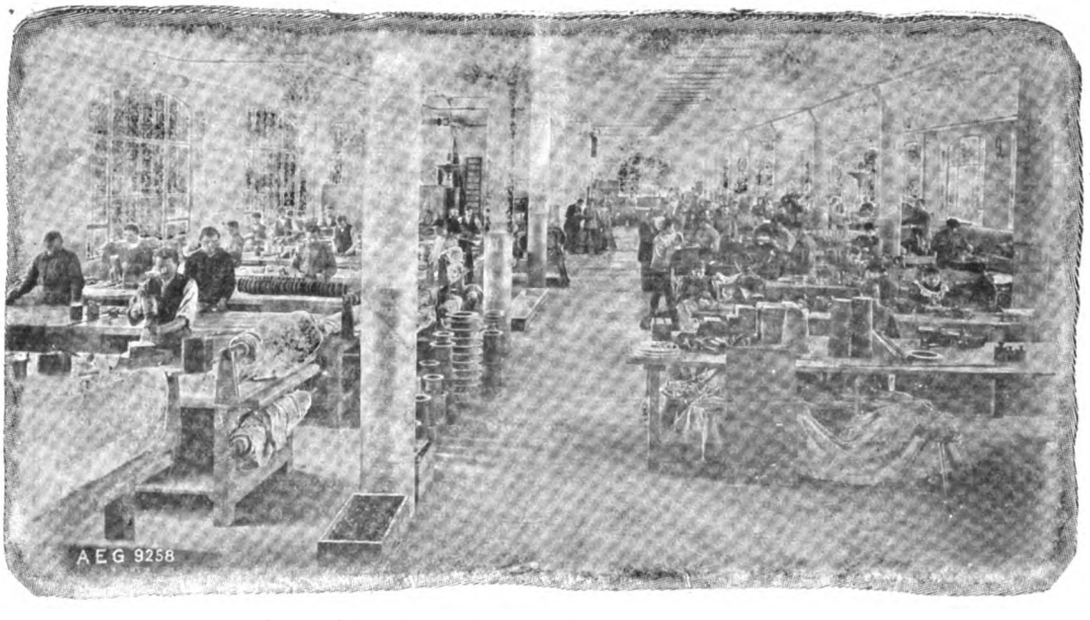

FIG. 6.—"Vulcasbeston" Insulation Department, Oberschoneweide.

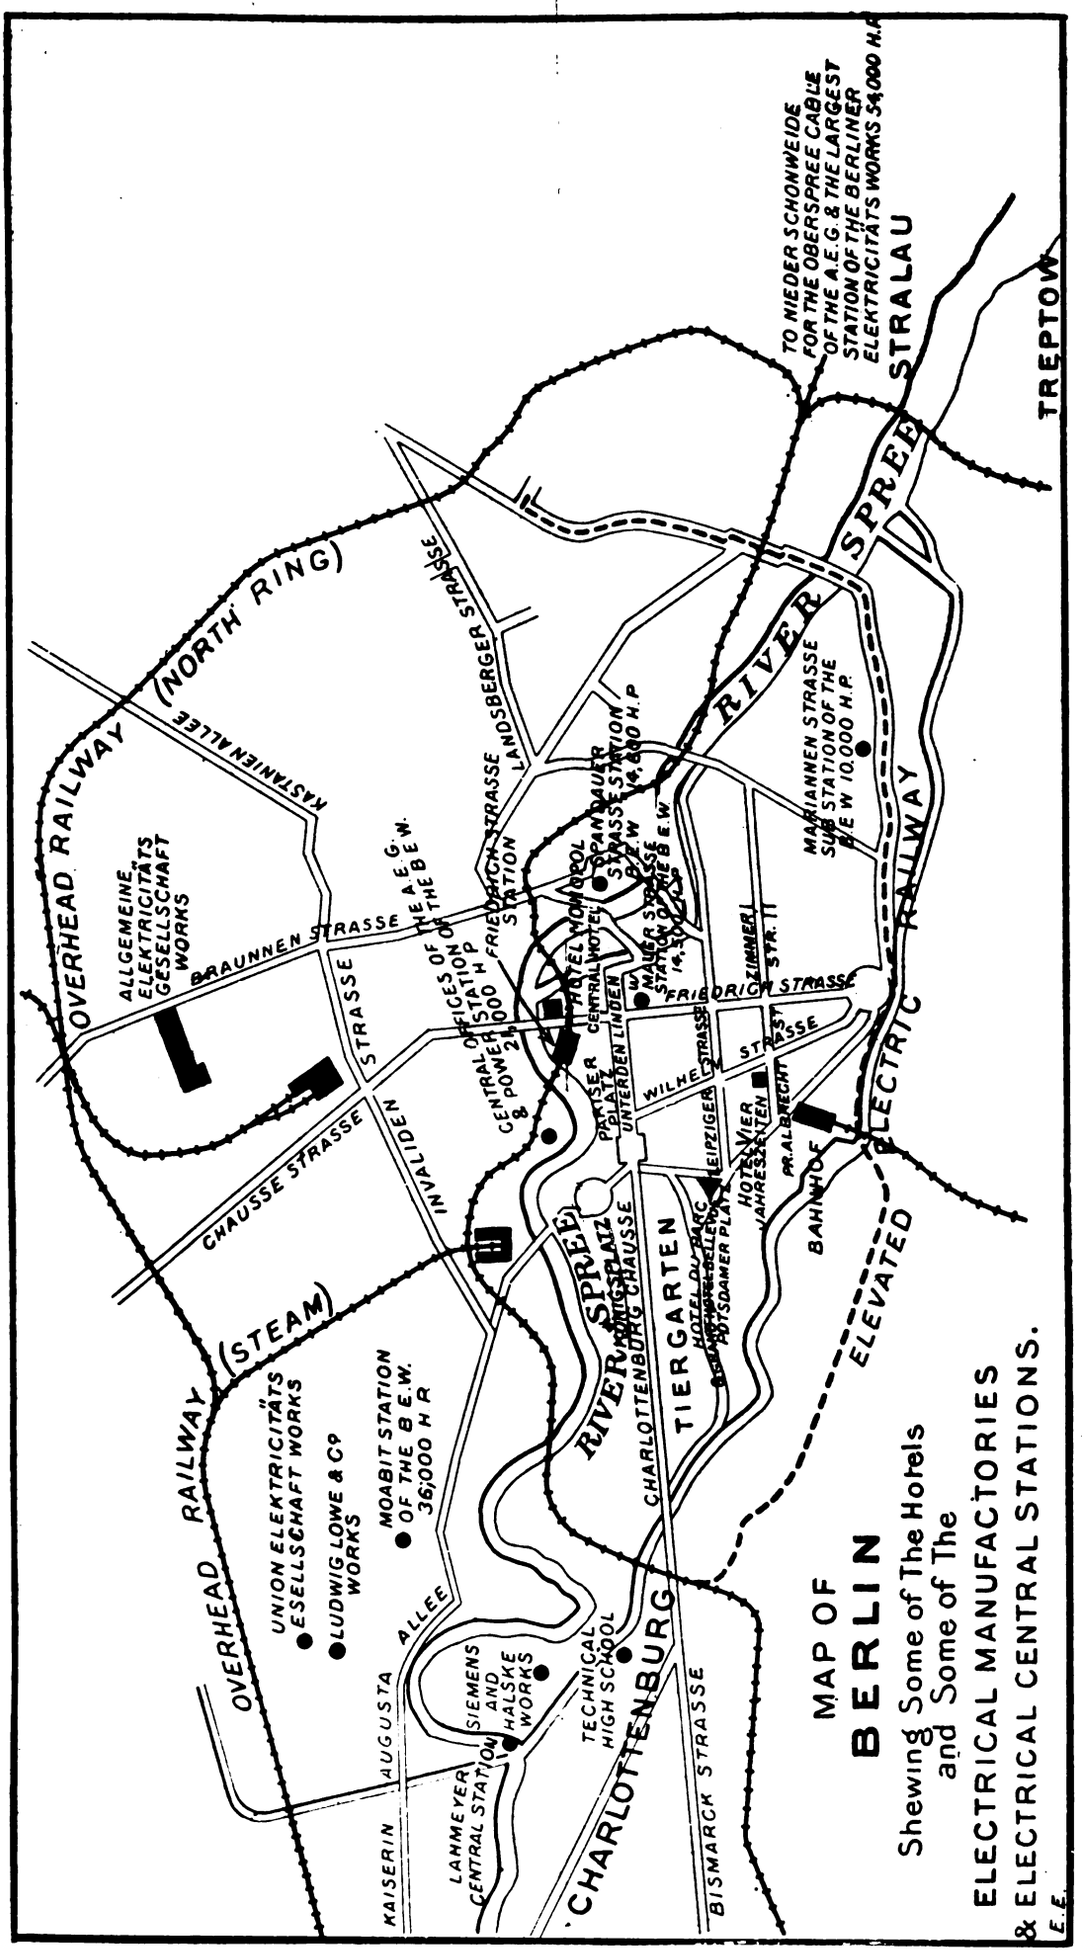
Digitized by Google

positions the wires are given first a seamless covering of strong vulcanised rubber, then a layer of rubber tape, a covering of cotton, and finally impregnated so that they are impervious to moisture. To protect wires against external damage, they are braided with fine steel wire. In addition to the cable and wire departments, the manufacture of all descriptions of insulating material is conducted at these works, including the Allgemeine



Digitized by Google

Elektricitäts Gesellschaft's special products, "stabilit" and "vulcasbeston." The processes of working up the raw rubber into its finished condition are very interesting. The raw material is shredded, purified, and dried in the vacuum ovens. It is then kneaded in the rolling mills (Fig. 5) and drawn through calenders into sheets 20m. to 30m. long and 800mm. wide. Stabilit is a special preparation, consisting principally of Para rubber; it possesses excellent insulating properties, is non-hydroscopic, and is very readily moulded. "Vulcasbeston" (Fig. 6) is a composition of stabilit and asbestos, and is capable of withstanding very high temperatures without injury. It is used very largely for transformer and field winding spools. In another department (Fig. 7) micanite paper and cloth is built up from flaked mica. An extensive use of this excellent insulating material is made in armature winding and commutator building.

In conclusion, we should like to mention the elaborate arrangements which exist for the comfort and welfare of the employés. In addition to the ambulance wagon and first-aid accessories, there is a very completely equipped hospital room, with a skilled man always in attendance. When the works were first started accidents were frequent, but as the workpeople became familiarised with the machinery the number of cases considerably diminished, and the attendant has been heard to complain of a slack time of late. Shower and other baths are provided free for those engaged in the more uncleanly operations; others can have the use of the baths by the payment of one halfpenny. Separate dining-rooms are provided for the management, the foremen, and for the male and female employés. Instruction is also given to the girls after working hours in needlework, etc., and periodical entertainments are also given. We feel sure that those who will have the pleasure of visiting these works will agree with the statement we made at the beginning of this article, that they are quite model in every respect.

Fig. 7.—"Micanite Insulation Department, Oberschoneweide.

CATALOGUES RECEIVED.

The General Electric Company have brought to our notice their new "Papriwire" insulation, which the firm intend to substitute in place of their "Excelsior" insulation. It is claimed for this new insulation that it is in every way equal to rubber insulation for bell wires in ordinary housework. These bell wires as supplied by the General Electric Company consist of high-conductivity copper wire, tinned, lapped with impregnated paper, and then braided with cotton and highly paraffined.

We have received from Messrs. Dorman and Smith their catalogue of electrical apparatus and accessories. These include different types of switches, circuit breakers, porcelain wall sockets, ceiling roses, lampholders, etc. We particularly notice in this catalogue a description of a new patent circular enclosed cut-out. These cut-outs are said to successfully stand any number of dead short-circuits at 250 volts. The arc blows itself out through a tunnel furnished at its end with the firm's wire-gauze vent. Without this vent, the flame which issues from the tunnel's mouth when the fuse blows is stated to be capable of setting fire to flimsy articles. We gather that the use of this wire-gauze vent is fully protected.

APPOINTMENTS VACANT.

Resident Electrical Engineer, Epsom Urban District Council, £3 per week, June 8. Full particulars in our advertisement columns.

Shift Engineer, electrician-in-charge for Canterbury electricity works, £78 per annum. Apply to Mr. N. Staniland, chief engineer.

Assistants (Two), Birkenhead Corporation electric tramways, 30*s.* per week, June 11. Apply to Mr. W. Bates, borough electrical engineer.

Chief Clerk, Wimbledon Urban District Council electricity department, £100 per annum, June 8. Apply to Mr. F. Barnes Spencer, electrical engineer to Council.

FORTHCOMING EVENTS.

FRIDAY, MAY 31.

Physical Society.—At 5 p.m., ordinary meeting.

MONDAY, JUNE 3.

Royal Institution.—At 5 p.m., general monthly meeting. Liverpool Self-Propelled Traffic Association. Trials of heavy motor vehicles commence. These will take place in the Liverpool and Manchester district on every day of the week up to and including Friday, the 7th. Monday: Hill-climbing tests at Everton and manœuvring tests at the Liverpool Docks. Tuesday: Liverpool to Manchester, *via* Warrington. Wednesday: Manchester to Liverpool, *via* Bolton. Thursday: Liverpool to Blackburn, *via* Chorley. Friday: Blackburn to Liverpool *via* Preston.

Society of Engineers.—At 7.30 p.m., ordinary meeting. Paper on "Concrete Subways for Underground Pipes," by Mr. A. Taylor Allen.

THURSDAY, JUNE 6.

Royal Institution.—At 3 p.m., Prof. Dewar on "The Chemistry of Carbon" (Lecture III.).

Rontgen Society.—At 8.30 p.m., general meeting. Paper: "X-Ray Diagnosis of Aneurism," with lantern demonstration, by Dr. Hugh Walsham.

FRIDAY, JUNE 7.

Royal Institution.—At 9 p.m., Prof. Raphael Meldola on "Mimetic Insects."

Accident.—Mr. and Mrs. W. B. Esson were thrown out of a trap at Maidenhead on Saturday afternoon last. Mrs. Esson was badly bruised and shaken. Mr. Esson escaped with little more than a sprain. We wish them both a speedy recovery.

THE VISIT TO GERMANY.

By the time these words are read most members of the Institution will have received the provisional programme of this visit. The work as arranged will test the physical condition of the members, even if the mental pabulum be taken as a pleasing change to the labours of each day. The *savants* of Germany have ever been in the forefront of scientific advancement, and its business men have never failed to stand similarly in applied science. We heartily welcome these international meetings. They introduce a better means of rubbing shoulders and exchanging opinions with men whose names are familiar as household words, broadening the minds and increasing the knowledge of all who take part in them. A healthy mind loves competition, and loves its competitors, luxuriating in friendly social intercourse. Neither the scientific man nor the business man cries out for official help, but prefers to work out his own aims in his own way to his own advantage. The man who is too old or too conceited to learn is too good to live. His position is with the angelic host, being of no further use in mundane spheres of life. On the other hand, the man whose brain is ready to receive new impressions, to discuss their value, to decide as to their use, is the man who is still wanted. Visits among other workers both in pure and applied science are object lessons, the value of each lesson being determined by the mental characteristic of the individual. There is much to see in Germany, and many details of practice to be studied by the visiting engineers. The provisional programme gives the arrangements made for three groups—one group ending the visit at Berlin, another at Dresden, and the third at Frankfurt-a-Main. Each day's work is sketched out, but as all members of the Institution will in the ordinary course receive a copy of the programme, it is unnecessary to give it at length. It will be enough to say that the party leaves England on June 22, *viâ* the Harwich and Hook of Holland route of the Great Eastern Railway, whose service, both as regards trains and boats, is probably the best that caters for Continental traffic. The detail arrangements have been placed in the hands of Messrs. T. Cook and Sons, whose great experience ought to ensure comfortable travelling. The estimated expense, so far as it can be estimated, is moderate in amount, and should ensure a full meeting. There are one or two points too often forgotten by those who take part in meetings of this kind, the principal, perhaps, being the enormous strain thrown upon the organisers, and this is made greater by the selfishness and carelessness of individual travellers who ought to know better. It seems ridiculous to accuse men of business, even when accompanied by ladies, of imposing upon the time and patience of the leaders of the expedition, and of neglecting the most simple precautions taken by individual travellers; but, unfortunately, this happens to far too great an extent. It should be held to be a privilege for every member to lighten the burden upon the officials as much as possible, and, so to speak, when in doubt, to forage for themselves. During the past

Digitized by Google

few weeks we have given some notes upon the visit and the places to be visited. These will be continued, and in this issue we give a sketch map which may assist members in obtaining an indication of the works to be visited in Berlin, and the principal points of guidance in that city.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BRIGHTON CABLES.

SIR,—Some weeks ago you published a series of letters which had passed between the Brighton Corporation and the Cable Makers' Association *re* the contract for the supply of cables to the former, which my company was fortunate enough to secure. I have waited to see whether any further letters would be published, but the correspondence appears to have stopped very abruptly.

The Cable Makers' Association stated and seemed to prove to their own satisfaction that the prices of the Union Cable Company, Limited, were higher in the aggregate than those quoted by some members of the association. It is impossible for anyone to say whether this is so or not without having the actual tenders for reference. I have a copy of the Union Cable Company's tender—which was in strict accordance with the Brighton specification—and, assuming that the members of the Cable Makers' Association based their tenders on the "standard" tables set out in the printed circular issued by the association in October last, their statement with regard to price would appear to require some further proof.

In making their comparison of prices, the Cable Makers' Association altogether ignore the question of conductor resistance, but, if they quoted in accordance with these "standard" tables, the resistance is a considerable factor in the calculation. The greater portion of the contract price is for one square inch conductor cable, of which seven miles are required. For this conductor (and for all others in proportion) the Union Cable Company, Limited, guaranteed a resistance of ·0422 ohm per mile at a temperature of 60deg. F., whilst the Cable Makers' Association guarantee only ·044176 ohm at ——— temperature. The "standard" tables omit all mention of the temperature at which resistance is to be measured, but if we assume that it is to be at the usual 60deg. F., then it seems to me that, all other conditions being equal, the value of the cables to the engineer is in inverse proportion to these resistance figures.

The Union Cable Company's resistance is 4·68 per cent. better than the Cable Makers' Association's, and as the Cable Makers' Association's lowest tender (£13,365) is only 4·2 per cent. lower than the Union Cable Company's (£13,952), it would appear, taking the one square inch conductor cable as a standard, that the Union Cable Company's tender really was lower than the lowest association tender by ·48 per cent. on the value of the cables alone. If we add to the association tender (*a*) cost of return of empty drums, and (*b*) the one-third cost of drums which the Cable Makers' Association insist on being paid in the event of drums being retained for a longer period than three months, even leaving out of consideration the fact that the buyers' engineer is buying exactly what he wants to buy, and not just what the seller wants to sell to him, I do not think there can be much doubt as to which is the more favourable tender for the buyer.

I trust that in fairness to my company you will be good enough to find space in your next issue for the above.—Yours, etc.,

J. A. BLACKWOOD,
Secretary to the Union Cable Company, Limited.

INSTITUTION OF ELECTRICAL ENGINEERS.

The report for the past year of the Council of the Institution of Electrical Engineers has now reached us, and it shows that many new departures have been made by the Council during the year. The report commences with a reference to the death of her Majesty Queen Victoria, and to the votes of condolence and loyalty which were passed by the parent Institution and its various local sections. After some notes as to the success of these local sections, including the new ones at Calcutta and Birmingham, reference is made to the lamented death of Prof. G. F. Fitzgerald. The increase in the membership of the society continues satisfactory. During the past 12 months there have been elected 21 members, 89 associate members, five foreign members, 140 associates, and 173 students, making a total of 428.

A long list of papers read is then given, and we are pleased to congratulate the following gentlemen on the premiums awarded them. These awards are: The Institution premium, value £25, to Mr. M. O'Gorman, member, for his paper entitled "Insulation on Cables." The Paris Electrical Exhibition premium, value £10, to Mr. W. Duddell, associate member, for his paper entitled, "On Rapid Variations of the Current through the Direct-Current Arc." The Fahie premium, value £10, to Mr. A. C. Eborall, member, for his paper entitled "Some Notes on Polyphase Sub-Station Machinery." An extra premium, value £10, to Mr. J. S. Highfield, member, for his paper entitled "Storage Batteries in Electric Power Stations controlled by Reversible Boosters." Four extra premiums, value £5 each, respectively to Mr. M. B. Field, member, for his (Glasgow Local Section) paper entitled "A Method of Compensating Voltmeters for Voltage Drop in Large Feeders"; to Mr. W. Wyld, associate member, for his (Birmingham Local Section) paper entitled "Polyphase Equipment of Factories"; to Mr. G. Ralph, associate member, for his (Newcastle Local Section) paper entitled "Electrically-Driven Machine Tools and their Advantages for Use in Engineering Workshops"; and to Mr. F. Holden, member, for his paper entitled "A Watt-Hour Meter." The first students' premium, value £10, to Mr. C. B. Nixon, student, for his paper on "Application of Electrical Power to Machine Tools." The second students' premium, value £5, to Mr. F. J. Hiss, jun., student, for his paper on "Recent Work on Hertz Wave Phenomena and its Application to Wireless Telegraphy." The third students' premium, value £5, to Mr. J. H. Vigor, student, for his paper on "Rotatory Converter Problems." An extra students' premium, value £3, to Mr. J. H. West, student, for his paper on "Accumulators." The Council has awarded two Salomons scholarships, value £50 each—one to Mr. J. D. Griffin, of the Central Technical College, and one to Mr. Herbert Ashlin Skelton, of King's College. The sum of £2,000, referred to in the last annual report as having been bequeathed by the late Prof. Hughes to found the David Hughes scholarship in the Institution, has now been received from the executors, and the Council has determined that for the present the manner of award shall be the same as that of the Salomons scholarship. They have selected Mr. C. J. Hopkins, of the Central Technical College, as the David Hughes scholar for the present year, the amount of the scholarship being £50. Mention is then made of the 20 students who were given £5 towards their expenses in visiting the Paris Exhibition. A list of these students is given, and also of the special class of exhibits about which each student had to write a report.

We learn that four sub-committees of the Council have been appointed, each consisting of one or two members, with power to add to their number. These committees are supposed to represent the following interests, and to see that good papers on the same are obtained: (1) traction, light, and power distribution; (2) telegraphs and telephones; (3) manufacturing; (4) electro-chemistry and electro-metallurgy. The Council also hopes that these committees will report on the relations between the Institution and their respective branches of electrical engineering, and on the special conditions or requirements for the time being of those branches. Reference is also made to the Paris visit, and to the welcome to the American Institute of Electrical Engineers. This institute has forwarded an illuminated address, which was presented at the meeting last night, and reads as follows.

Digitized by Google

The American Institute of Electrical Engineers has the honour to transmit with fraternal greetings to the Institution of Electrical Engineers of Great Britain the following resolutions:

Whereas, the American Institute of Electrical Engineers during the visit of its members to London and Paris in connection with the International Electrical Congress of 1900, and also in connection with the joint meeting immediately preceding the same of the British Institution and American Institute of Electrical Engineers held in Paris on Aug. 16, 1900, was the recipient of many courtesies and much hospitality from the British Institution of Electrical Engineers,

Resolved, "That the American Institute of Electrical Engineers herewith respectfully tenders to the Institution of Electrical Engineers of Great Britain its sincere thanks for the many courtesies extended to its members in connection with the above-mentioned visit to London, and with the joint meeting of the two institutions in Paris, both of which have left many pleasurable recollections."

Resolved, "That a copy of these resolutions be forwarded to the Institution of Electrical Engineers in London, and that a copy of the same be published in the *Transactions* of the American Institute of Electrical Engineers."

The above resolutions were unanimously adopted at a meeting of the Council of the American Institute of Electrical Engineers held in New York City, U.S.A., March 22, 1901.

(Signed) CARL HERING, President.
RALPH W. POPE, secretary.

Three special committees of the Council have been elected, dealing with the following three subjects: (*a*) the revision of the wiring rules; (*b*) the drawing of model general conditions for electrical contracts; (*c*) the general matters arising out of Mr. W. L. Madgen's paper on the Electrical Power Bills. There are many other items of interest in the report, but the last to which we can refer is the formation by the Council of an employment register. This latest move is open to some objection, as will, we believe, be found after a year or two of experience.

The following is an abstract of the receipts and expenditure account and of the balance-sheet for the past year:

STATEMENT OF RECEIPTS AND EXPENDITURE.

Dr. Receipts.	£ s. d.
Annual subscriptions	5,126 8 0
Entrance fees	596 17 0
Cash balance paid by Northern Society of Electrical Engineers	184 12 7
Advertisements in the *Journal*	72 0 0
Publishing fund	1 1 0
Dividends on investments—viz.: life compositions, £153. 15s. 10d.; general fund, £113. 11s. 8d.	267 7 6
Interest on cash on deposit	17 2 1
	£6,265 8 2

Cr. Expenditure.		£ s. d.
Salaries		891 13 6

THE PROTECTION OF OVERHEAD TRAMWAY CONDUCTORS.

The recent accident at Liverpool has brought to the front a number of inventors who have worked on the great question of the protection of the public from all such dangers as resulted from the fatal accident in that city. We have already described some four or five devices having for their object either the disconnection of a trolley wire from the main supply in the event of a telegraph or telephone conductor falling across them, or the insulating of the broken ends of the trolley wire in case a fracture should occur. This week we have had information forwarded to us from two other inventors. The first apparatus now under consideration is that manufactured by Messrs. Bostock and Cheetham, of Brighouse, Yorks. The manufacturers of this safety device have recently experimented with it at Hull, where successful trials were made to prove that the ends of a broken trolley wire were quite dead before they reached the ground. The arrangement requires, however, that each span shall be independent of its neighbours. It is decribed by its inventors as follows: Attached to the arm of the overhead wire by means of an insulated clip is a frame, in the centre of which is an upright piece to which a pair of weighted L lever

Digitized by Google

arms are hinged and insulated. Each inner arm of the lever is connected by a hinged link with a block free to slide within the frame, the inner face of each block being insulated, and the outer face of each block carries a hook to which the overhead wire is attached. The communication way for the wheel or pulley for taking the electricity from the wire is made by means of a pair of hinged concave arms, which are held in position by means of two loops and two hooked pins which engage in the said loops, holding them in a horizontal position, so that a continuous wheel race is provided from one length of wire to the next length of wire. The action is as follows: In the event of a wire breaking, there being no longer tension on the wire and hook, the lever arm of the broken wire falls, and through its fall gives motion to the connecting link, and draws back the block in its side until the inner end of the block is brought into contact with an insulated case of the upright, and the current is shut off instantly and automatically. The same current of the slide piece withdraws the hooked pin from the loop of the concave arm, which at once falls into a vertical position and so moves clear of the broken wire.

From the illustration which is given by Messrs. Bostock and Cheetham, it would seem that the device is chiefly adaptable for side-pole suspension, as the weight of the levers and switch gear would be very heavy to carry on a span wire. The apparatus is, of course, only intended as a protection against a broken wire, and does not at all effect the protection of the public if a telegraph or telephone wire falls down on the trolley wire without breaking it. The chief disadvantage, in our opinion, in the device is that a continuous trolley wire is not employed. It also adds somewhat to the unsightliness of tramway construction, which is a matter for consideration in most towns.

The other device brought to our notice is that of Mr. C. J. R. Mesurier, of 19, Perrymead-street, Fulham. Of this device we have received a diagrammatic sketch, as shown in Fig. 1. It is particularly impressed upon us that this sketch is merely to show the arrangements, and not the actual details of the design of the electrically controlled switch release and electromagnets. The inventor's description of the apparatus sent us with the drawing is as follows: "A is the main overhead wire, B B guard wires, which are not merely a mechanical protection, but are insulated, and form a complete loop circuit, through which the battery, C, maintains a small but uninterrupted current; *b b* are non-conducting attachments, linking the main overhead wire, A, to the guard wire, B, so that in the event of the main, A, falling it would sever and carry with it the guard wire, B. D is a main switch between the generators and the main A; F is an electromagnet in circuit with the battery, C, and loop guard wire, B B; G is a larger electromagnet, which comes into action only under certain conditions. The working of this safety system is as follows: the battery, C, constantly maintains a small current through the loop guard wire, B B, the connection between the generator and the main overhead wire, A, being made dependent on the continuity of this loop circuit. This is effected by arranging that the powerful spring, H, will instantly actuate the main switch whenever the latter is freed by the release of the detent, K, which is held permanently latched by the electromagnet, F, through which the small current of the battery, C, is uninterruptedly maintained. The larger electromagnet, G, with an earth connection, E, is merely to provide for the case of a telegraph or telephone wire falling across (without severing) the guard wire, B B, and connecting it with the main overhead wire, A. A large current would then instantly pass through the electromagnet, G, which would overpower the small electromagnet, F, drawing the armature away from it, thus actuating the pivoted lever, M, and releasing the detent of the main switch. Apart from the falling across the system of telegraph or telephone wires, there is the possibility of a section of the main overhead wire becoming detached from the supports and trailing in the roadway. In this case also the main circuit would be broken.

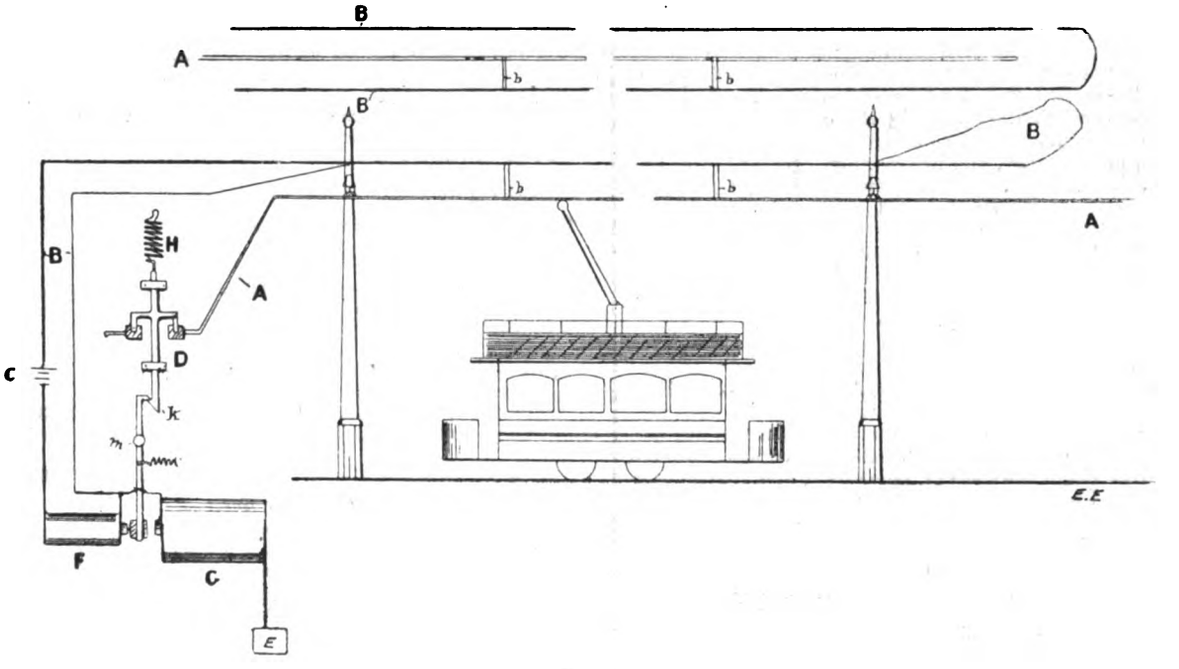

FIG. 1.

as the falling wire must necessarily carry with it and thus sever the guard wire, B, by virtue of the non-conducting connecting links, *b b*."

We have had an engineer representing the inventor to see us, and have discussed the details of the device with him. We gather that the guard wires over each section of the line controlled from a switch pillar would be connected up in a ring, and that the inventor claims a great advantage from having a current circulating in this ring, because in the event of the wire becoming broken the high-voltage current would immediately be cut off the trolley wire underneath it. Our objection to the device is the suggested weakness of the guard wires, which are supposed to break in the event of the trolley wire becoming fractured. It is conceivable in our opinion that it would require exceedingly delicate handling when erecting these guard wires in order to so adjust the tension that the weight of the length of trolley wire, which would be supported by the insulators from the guard wire, would be sufficient to cause a fracture. Assuming that it could be done, there would then be the question as to whether wind and snow would not cause endless trouble by interrupting the guard wires and throwing off the switches. It was suggested to us that the difficulty referred to could be overcome by having the ends of the guard wires secured to a plug held in a sleeve with a spring grip, which could be adjusted

Digitized by Google

to release when a slight addition to weight was put on. On the whole, it seems to us that the electromagnet through which the current would pass to earth would really give the most protection, and that the current circulating in the loop has not really the advantages which at first sight would appear. Of course, unless the mechanical conditions of making the guard wires give way when a trolley wire breaks can be overcome, the device does not give the protection which is desired in such cases, but it would still protect against telephone wires which make contact with both the trolley and guard wire.

ELECTRIC TRAMWAYS FOR LEICESTER.

Report of Mr. E. Manville, M.I.C.E.

(Concluded from page 752.)

Situation of a Generating Station.

I have gone very carefully into the relative advantages of an independent central power station, a power station in connection with the existing Corporation gas and electric light works at Aylestone, and a combination of the various dust destructor installations existing in the borough with electric generating stations, supplemented by coal-fired boilers. Dealing in the first place with the last proposal—*i.e.*, the production of as much as possible of the electrical energy required for the tramway from steam raised by the various dust destructors, and supplementing these with coal-fired boilers installed at the dust destructor stations—I have considered this very carefully, and am absolutely satisfied that any advantages that might accrue to this system through the saving in the consumption of coal would be so much more than counterbalanced by extra capital expenditure, maintenance, and increased charges of labour and supervision, that I could, under no circumstances, recommend it to your serious consideration, and I am of opinion that this alternative may be entirely set aside. The question, therefore, resolves itself into the consideration of the two other alternatives of an independent station situated at a site favourable for distribution to the tramway system and of the installation of the requisite machinery, as an addition to, and in conjunction with, that required for the generation and distribution of electricity for lighting and other purposes at the present existing gas and electric light works at Aylestone. In order to arrive at a conclusion on this important subject, I have inspected the gasworks site and existing power station, and also the site adjoining the Lero dust destructor, and I have since worked out in complete detail the costs of generation and distribution for both sites. I have also prepared detailed schemes and estimates of the sizes, arrangements, and costs of an efficient system of feeders and distributors for the tramway system. Appended to this report are plans of the mains and distributors that would be required in both cases, and charts showing the loss in E.M.F. that would be occasioned by the use of either system, from which will be gathered the efficiencies I am proposing in both cases. Recognising as I do the importance of this question, I have thought it better to go into complete detail rather than to make approximate estimates.

The following, then, are my two estimates of the capital expenditure and costs of production in the cases of the respective sites :

General Data.

Cars in service	85
Probable number of car miles run per annum on the basis of the various services indicated on the plan herewith	2,922,920
Average amount of electrical energy per car mile, including power required for battery charging, sundry motors, lighting in power stations, car-sheds, etc., and including losses in low-tension feeders	1 B.O.T. unit
Therefore kilowatt-hours to be generated per annum : (*a*) continuous-current power station situated on Lero site	2,922,920

(*b*) High-tension power station on gasworks site to be supplied to low-tension tramway feeders after transmission and transformation.

From	B.O.T. units supplied to low-tension feeders.		B.O.T. units generated.
Gasworks site	674,500	.....	758,000
Lero sub-station	1,318,300	.....	1,550,000
Highfields sub-station	930,140	.....	1,100,000
	2,922,900	.....	3,408,000

or, say, 3,410,000 Board of Trade units generated per annum.

It will be observed that the difference between the Board of Trade units supplied to the low-tension feeders at the gasworks and two sub-stations differs from the high-tension Board of Trade units generated at the gasworks, the difference representing the losses in transmission and transformation.

Lero Site.

Estimated Capital Expenditure for Low-Tension Power Station on Lero Site and Low-Tension Feeder System in connection therewith :

	£
Boiler-House Plant.—Five Lancashire boilers, complete with mountings and erected on settings ; complete system of steam, feed, drain, and water pipes, with valves, etc. ; feed pumps, economiser, tank, and sundry ironwork ; coal and ash conveyor plant, automatic stoker gear, and overhead coal store	19,210
Engine-House Plant.—Three direct-driven generators, each 375 kw., at 500 to 550 volts, coupled to vertical medium-speed engines, complete with separately-driven surface-condensing plant ; complete system of exhaust, intake, and discharge pipes, and sundry ironwork ; battery of accumulators to absorb the fluctuations in load, having a discharge capacity of 630 amperes for one hour ; switch-board, consisting of the necessary feeder panels, generator panels, negative booster panels, battery panel, Board of Trade panel, etc., with connections, testing instruments, etc. ; booster for charging battery and negative boosters	22,900
Travelling crane, tools, spares, etc.	800
Total for plant	42,910
Feeders.—Positive : 9,040 yards ·2 square inch, 9,000 yards ·3 square inch, 3,300 yards ·15 square inch. 11,330 yards ·1 square inch, 6,580 yards ·25 square inch, 2,550 yards ·35 square inch, including drawing in and jointing	8,740
Negative : 1,100 yards ·5 square inch, 4,930 yards ·4 square inch, including laying on the solid filling-in system	2 647
Telephone and pilot wires—28,000 yards three core, 8,000 yards four core, including drawing in and jointing	1,848
Excavation and reinstatement of roadways and pavements, 29,000 yards at 3s. 6d. per yard	5,100
Stoneware pipes for above system of positive feeders, laid and jointed	2,373
Brickwork drawing-in boxes, with frames and covers, feeder switch pillars, and section boxes	5 340
Total for feeders	26,048
Total	68,958
Engineering and contingencies, 10 per cent.	6 896
	£75,854

Estimated Cost of Production of 2,922,920 Board of Trade Units, including Interest on Sinking Fund at 5½ per cent. on Capital employed.

	Pence per unit.	£	s.	d.
Coal, water, oil, waste, and sundry stores ; wages, including supervision, repairs, and maintenance	·66	8,037	8	0
Interest and sinking fund, 5½ % on £75,854	·358	4,361	12	0
Total	1·02	£12,399	0	0

Gasworks Site.

Estimated Capital Expenditure for High-Tension Power Station on Gasworks Site, High and Low Tension Feeders, and Sub-Station Plant in connection therewith.

	£
Boiler-House Plant.—Five Lancashire boilers, complete with mountings, and erected on settings ; complete system of steam, feed, drain, and water pipes, with valves, etc. ; feed pumps, economiser, tank, and sundry ironwork	10,210
Engine-House Plant.—Three direct-driven two-phase alternators, each 450 kw. at 2 000 to 2,200 volts, coupled to vertical medium-speed engines, with exciters ; complete surface-condensing plant, together with exhaust, intake, and discharge pipes, and sundry ironwork ; two 165-kw. rotary converters with complement of static transformers ; battery of accumulators having a capacity of 95 kilowatt-hours ; battery-charging motor booster ; main switch-board, comprising the necessary high-tension generator, and high and low tension feeder panels ; transformer battery and Board of Trade panels, etc., connecting cables and testing instruments	26,175
Tools and spares	750
Lero Sub Station.—Three 165-kw. rotary converters with complement of static transformers ; one battery-charging motor booster ; one negative feeder booster ; battery of accumulators having a capacity of 190 kilowatt-hours ; main switchboard, comprising high-tension receiving and transformer panels, low-tension feeder and generator panels, battery motor booster and Board of Trade panels, cable connections, etc.	8,583
Highfields Sub-Station.—Three 115-kw. rotary converters with complement of static transformers ; one battery-charging motor booster ; battery of accumulators having a capacity of 140 kilowatt-hours ; main switchboard, comprising high-tension receiving and transformer panels, low-tension feeder and generator panels, battery motor booster and Board of Trade panels, cable connections, etc.	6,325
Total for plant	14,903
Feeders.—High-tension two-phase, 8 140 yards ·10 by ·10 by ·141 sq. in., 7.760 yards ·066 by ·066 by ·093 sq. in.	6,870
Low-tension : 3,097 yards ·05 square inch, 16,052 yards ·10 square inch, 8,419 yards ·125 square inch, 6,291 yards ·150 square inch, 2,710 yards ·175 square inch, including drawing in and jointing	4,410

Digitized by Google

Telephone and test cables—15·7 miles three-core, 57 miles four-core, including drawing in and jointing	1,439
Excavation and reinstatement of roadways and pavements—27,000 yards, at 3s. 6d. per yard	4,730
Stoneware pipes for above system of high and low tension feeders, laid and jointed	2,300
Brickwork drawing-in boxes, with frames and covers, feeder switch pillars and section boxes	4,860
Total for feeders	24 609
Total	76,652
Engineering and contingencies, 10 per cent.	7 665
	£84 317

Estimated Cost of Production of 3,410,000 Board of Trade Units including Interest and Sinking Fund at 5¾ per cent. on Capital Employed.

	Pence per unit.	£	s.	d.
Coke, water, oil, waste, and sundry stores; wages (including supervision), repairs, and maintenance	·614	8,723	0	0
Interest and sinking fund (5¾ per cent. on £84,317)	·341	4,848	0	0
Total	·955	£13,571	0	0

The foregoing estimates are founded on the basis that if a separate generating station at the Lero site is erected, current will there be generated at a pressure of from 500 to 550 volts, and distributed directly to the trolley wire through low-tension distributors; whilst if the gasworks proposition is adopted, high-tension two-phase plant would be installed at the gasworks, producing electrical energy at a pressure of about 2,000 volts each phase. Static and rotary transformers would then be installed on the gasworks site to feed that part of the tramway system nearest the gasworks site with low-tension continuous current, as shown on the plan of the mains accompanying this report; and high-tension transmission lines in duplicate would be run from the gasworks site to two sub-stations, situated one at or near the Lero site and the other in the neighbourhood of Highfields, in both of which sub-stations transformer plant similar to that installed at the gasworks would be erected, and each sub-station would have its own low-tension system of distribution to those portions of the system taking energy from the respective sub-stations. In the estimate of capital cost I have entirely eliminated the cost of buildings. The buildings of the gasworks site monopolised by the machinery for supply to the tramways would cost less than the buildings on the Lero erected expressly for the purpose of the electric generating station; but, on the other hand, if the supply were effected from the gasworks site, the two sub-stations near Highfields and near the Lero site would have to be erected, which would, in my opinion, just about counterbalance the extra cost of the buildings of the Lero power station over those at the gasworks.

From the estimates, your Council will observe that the capital that would have to be expended by the Corporation, exclusive of buildings—in the case of the power being generated at the gasworks—would amount to £84,317, whilst in the case of the separate power station on the Lero site, the capital to be expended would amount to £75,854. The larger expenditure in the case of the gasworks site, of course, tells on the cost of the energy generated, when interest and sinking fund is added, as compared with the smaller cost of the other station. The total costs, including interest and sinking fund, amount on the whole to ·95d. per unit in the case of the gasworks site, or a total sum per annum of £13,571 and 1·02d. per unit for the Lero site, or a total expenditure of £12,399 per annum. It will be observed from these figures that the cost of the unit generated at the gasworks site—even including the extra capital expenditure—is less than the cost per unit if the current were generated at the Lero site, and this notwithstanding that in the estimate of maintenance at the gasworks site is included the requisite wages for attendance at the two sub-stations. But this saving in the cost of generation at the gasworks site over that at the Lero site is more than counterbalanced by the larger number of units required to be generated at the gasworks site to allow for the losses in the high-tension transmission and the ultimate transformation to low-tension current, this in the end giving the Lero site an annual advantage on the estimated car service of £1,172 per annum. In making these estimates of maintenance I have taken the cost of coke at the gasworks at the average of the prices obtained by the gas department for the surplus coke during the last 10 years, and in the case of the Lero site I have taken in the same manner the average price paid for engine slack at the sewage works for the last seven years, and I have further been careful to allow what I estimate to be the full difference of calorific value in favour of the coke over the engine slack. If, however, it be ultimately decided to erect the generating station on the Lero site, and it should be found that coke could be more economically used than engine slack at the prices charged by the gas department for the surplus coke, there would be no reason why coke should not be used there in place of engine slack. The calculations of the costs of the low-tension feeders, with either site, are on the basis that the overhead trolley system is used, and not the conduit system, as mentioned earlier in this report. If a conduit system be used, it becomes necessary to abandon the rails as a return system, and to use an insulated return circuit, with a consequent considerable increase in the cost of the low-tension feeders; and I find that this increase would be in the case of the Lero site £15,568 above the cost with the overhead trolley system, and in the case of the gasworks site, with the distribution from sub-stations, £11,404, maintaining in both cases the same efficiency of distribution as in the case of the overhead trolley system. The above figures point distinctly to the better economy that would be achieved in both capital and costs of production if the Lero site be adopted in place of the gasworks site; but there are other considerations which accentuate this fact, as follows: the difference in cost between the current generated on the two sites in favour of the Lero site is calculated on the number of car miles likely to be run on the tramway system soon after its completion, as at present contemplated; but when, as is tolerably certain will be the case, both the services and the length of lines of the tramways are increased in the future, this difference in cost will become proportionately larger.

The direction in which the extensions at Leicester are progressing will tend to make the Lero site more and more a centre, so far as the ultimate tramway system is concerned, which will reduce the cost of the feeders required from this site for further extensions as compared with the gasworks site. The system that would be used in conjunction with the Lero site is the simplest and most reliable, involving the fewest number of moving parts to depend on, and being entirely without the extra risk always present when high-tension transmissions of electrical energy have to be employed, although, of course, this would not affect the question seriously, especially with the provisions I have made in my estimates for duplicating high-tension feeders, were there any appreciable saving to be made by taking a supply from the gasworks site. Perhaps, however, the most important point of all is the fact that in these comparative estimates I have given only the estimated costs of production of the current, together with interest and maintenance on the plant employed, with both of the proposed plants. It is, however, hardly to be expected that the gas department would be content to supply the tramways with current at this estimated cost of production, which at the best would only just cover their out-of-pocket expenses. I understand from Mr. Colson that he thought his committee would be prepared to supply the tramways with current, should their site be selected, at a price not exceeding the present works cost of the current sold to private consumers from his electric supply station, and which amounted in 1900, according to the figures he has furnished me with, to 1·75d. per Board of Trade unit. Obviously this price, or anything approaching it, would mean such a very large increase on the rates at which the Tramway Committee could generate current for themselves at the Lero site that it would put the taking of a supply from the gasworks site out of the question. There is yet another point in favour of the Lero site, and that is the fact that the heat generated by the cremation of refuse in the destructor might be utilised for saving a part of the fuel I have estimated as being required on this site. By the additional expenditure of £3,600 over and above my capital estimate for the Lero site three new tubular boilers might be added, and a further two cells and a Babcock and Wilcox boiler, which would enable steam to the value of about 200 i.h.p. to be realised, whilst at the same time the two extra cells would enable a further quantity of the town's ashbin refuse to be cremated at this destructor. The above extra expenditure is arrived at by deducting the cost of one of the Lancashire boilers—which would not then be required—from the cost of the additional work to the destructor. As regards the relative facilities at the gasworks, and on the piece of ground adjoining the Lero destructor for accommodating the generating plant, I have inspected both sites, and given consideration to the subject, and I attach herewith a sketch plan showing at least one way in which the piece of ground adjoining the Lero destructor might be utilised for accommodating the plant that would be required for the tramway system, as at present contemplated, with room for further considerable extensions, without acquiring the strip of land at present occupied by the limekilns, which would, should it ever be desirable in the future, allow of still greater extensions being made there.

At the gasworks there is also ample room for the accommodation of the tramway plant, though if the demand for electrical energy for private purposes increases constantly in Leicester, as it is likely to do, the time may rapidly approach when either the tramway plant should be accommodated in a separate building from the electric lighting plant, or the extensions of the electric lighting plant be placed in a second building, in either of which cases some of the economies of the combination of the two systems would disappear. On the gasworks site there exists a well-equipped workshop, in which repairs of all

Digitized by Google

machinery can be very economically affected, and that is an advantage which would pertain to the selection of this site. On the other hand, if a separate generating station be erected on the Lero site, it will be within a very short distance of the principal car depôt, where a very complete equipment of tools will necessarily have to be provided, and having regard to the very small number of repairs that are required in connection with electric generating plant of the best description, I do not consider that the question of possessing a fully-equipped workshop on the spot, or within a short distance of it, would make any material difference.

I trust that the particulars I have placed before your committee in this report will enable them to come to a definite conclusion on the matters referred to me. I would further point out that, should they decide on installing the conduit system, they could not alter it in the future in favour of one of the surface contact systems, should that become in the future entirely practicable. In fact, the whole of the tramway would want entire reconstruction, and only the rails would be available when the change were made. On the other hand, should they decide to adopt the overhead trolley system for the present, and the surface-contact systems become practicable in the future, there would be no difficulty in replacing the overhead sytem, in any part of the town where it was thought desirable, with a surface-contact system at very little expense over and above what would be incurred were that system installed at the outset; whilst the steel standards and overhead gear, which in that event would be dispensed with, could be sold for a large proportion of their original cost, and the profits made out of the tramways with the overhead system during the first few years would certainly more than compensate for any loss of capital involved. The difference in capital cost between the conduit system and the overhead trolley system of at least £357,000 represents an extra annual payment, by way of interest and sinking fund, at 5¾ per cent. of, say, £20,500; and so long as the car miles run on the length of tramways proposed did not exceed 3,000,000 this extra payment would represent an extra cost of nearly 1¾d. per car mile; whilst if the overhead trolley system is installed, either the fares could be reduced by this amount or the very large sum which it represents could be utilised for the reduction of the rates.

You have not asked me to investigate the financial prospects of the tramways in Leicester, when extended and electrically equipped, but from the inspections I have made I should like to state that it is perfectly obvious that, with the installation of the trolley system, the tramways cannot fail to be a most remunerative investment for the Corporation. The time taken in reconstructing and electrically equipping the Leicester tramways, on whichever system may be adopted, must necessarily be considerable, and as the complete system can hardly work smoothly and be of full advantage to the town until the re-equipment is completed, I think it would be very desirable that the whole of the work should be carried out as quickly as possible, section after section being put to work as completed.

In conclusion, in my opinion it will be best for your Council (1) to adopt the overhead trolley system of electrical traction; (2) to erect a separate power station for the purposes of the tramways on the Lero site. I should like to express my thanks to Mr. Colson, the gas and electric light engineer, and Mr. Mawbey, the borough engineer, for the great assistance they have afforded me in making the necessary investigations into the matter, and for the trouble they have taken in providing me with the requisite data. (Signed) E. MANVILLE.

The above report was considered in detail by the Tramway Committee, who recommended to the Corporation that the same should be adopted in full, and that Mr. E. Manville, of the firm of Kincaid, Waller, and Manville, should be appointed consulting engineer to carry out the work.

On Tuesday, May 21, this report of the Tramways Committee came up before the Council for discussion. Its adoption was moved by Councillor FLINT, who gave a brief *résumé* of the steps which had led the committee to call in expert advice. He explained that out of six names submitted for the consideration of the committee that of Mr. Manville was unanimously agreed upon. He added that he knew from careful enquiry that Mr. Manville was favourably disposed towards combined power stations, but he considered him an independent expert in whom they could have complete confidence, and whose decision might be loyally accepted. Councillor Flint then referred to the figures mentioned in the report to show how much more expensive the conduit system was than the overhead trolley system. He finally urged the Council to support the committee, so that the Bill for new powers could be deposited in Parliament before next November, otherwise it would be three years before the system could be in operation, whereas a prompt decision would allow of the work being done in two.

The resolution proposed by Councillor Flint was then seconded by Councillor T. SMITH.

The MAYOR, in opposing the motion, expressed his regret that he had to take up the matter, but owing to the large outlay proposed of £400,000, felt that he could not be only a listener. He urged that they should go slowly with respect to the electrical equipment, improving the present system in the meanwhile. While they would like to have the conduit system, if its cost were not prohibitive, he had never ventured to hope for more than a surface-contact system, and that only in the centre of the town. He regretted that there was not more in Mr. Manville's report concerning the Dolter surface-contact system, which was already in work in Paris. He had had good reports of the working of this system during the past winter. He had received a letter addressed to him by Mr. E. Garcke, chairman of the Dolter Company, offering to equip a line or lines in Leicester at the company's expense on the condition that if it were not satisfactory it should be removed, and if it were satisfactory it should be paid for at an agreed price. The Mayor said that there was no man holding a prominent position in the electrical world who did not recognise that the trolley system was doomed, and he personally believed that it would be prohibited by the Board of Trade as soon as a reliable surface-contact system or a cheap conduit system were available. The next point taken up by the Mayor was the question of the power station. He objected to Mr. Manville quoting the figure of 1·75d. per Board of Trade unit as the price at which the Gas Committee would be prepared to supply electricity to the Tramway Committee. Mr. Colson was said to have supplied this, but the matter had not been discussed by the Gas Committee. He also objected to Mr. Manville assuming that high-tension transmission would be required if the generating station was placed at Aylestone, because the Gas Committee had not decided what plant they would put down. In the estimated expenditure on the Lero site of £75,854, Mr. Manville had not included the cost of new buildings, which he (the Mayor) estimated at £10,000. They would also have to buy a new site to build car-sheds, at a cost of £5,239, whereas if they used the Aylestone site for the generating works, the Lero site could be used for the car-sheds. This brought the capital outlay on the Lero site to £91,193, while the capital cost at Aylestone was estimated at £84,317. He estimated the additional buildings required at Aylestone would only cost £5,000. They would not require more than one sub-station, and he concluded that with the Aylestone site the first cost would be £17,376 less than with the Lero site. As regards the running expenses, the extra plant at Aylestone would, the Mayor estimated, only amount to £7 per week, whereas the cost of labour in the proposed station at Lero would be at least £23. 10s. per week, which meant a saving of £858 per annum. With a saving in the carriage of fuel of £260, and together with the interest in sinking-fund charges of the decreased capital cost, the Aylestone site showed an advantage of £2,169 per annum. He did not dispute Mr. Manville's figures, but considered that they were founded on an assumption which did not exist. He, therefore, asked that the report should not be passed that night, and that the committee should adopt the Aylestone site as the cheapest and best.

Councillor WALTERS held that the Mayor ought to have given the information he had collected to the Tramway Committee rather than in full Council, as Mr. Manville was present at the committee, and could have been examined with regard to his own figures and also those brought forward by the Mayor. With regard to the two sites, the Mayor could not in one breath claim that it was an advantage to go to Aylestone to utilise the present machinery, and in the next state that they did not propose to use the present machinery at all. Again, on the question of buildings, he disputed entirely the Mayor's figures, as the cost of the buildings would be the same in each case, being proportional to the cube contents. Again, the growth of Leicester was not in the direction of Aylestone, but rather in the other direction, so that the station would become more inconveniently situated as time went on. The Lero site was not only the best under the present conditions, but also it would be about the centre of gravity of the area in the future. Seeing that the current required for the tramways was not the same as that generated at Aylestone, he thought it would be better not to have one staff for the two systems. As regards the need for expert advice, they had chosen their expert, who, he believed, had a bias in favour of an underground system. Having then obtained an expert's advice, he thought it was time to act. They had quite enough evidence before them to enable them to decide, and he hoped they would go forward with the unanimous vote of the Council to get their Bill in Parliament next year.

Alderman WOOD, knowing the urgent necessity there was for improving the tramway system, suggested they should accept the report with the exception of the position of the site. After a long debate, in which most unnecessary personal remarks were made, this course was agreed upon. In the course of this debate it was elicited from the Mayor that he had received assistance from an expert as well as from Mr. Colson, and that he proposed to have this expert present at the committee meeting. This raised the question as to whether each private member could retain his own expert and have him heard at the deliberations of the committee.

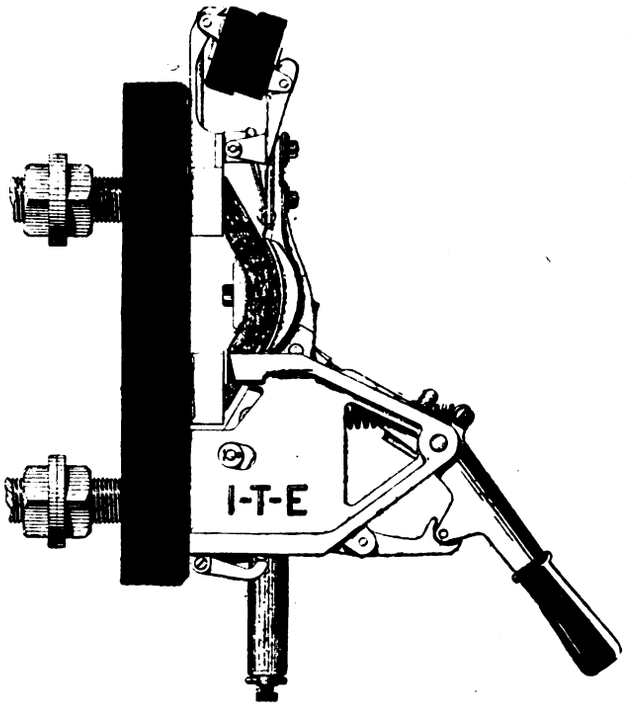
"I. T. E." CIRCUIT BREAKERS.

Messrs. R. W. Blackwell and Co. have recently published a complete list of circuit breakers, which they are supplying in this country under the general name of "I. T. E." circuit breakers. The first thing which an electrical engineer wants to know is, what is the meaning of these letters. They refer to the fact that with these circuit breakers the heavier the excess current is over the normal, the shorter will be the interval of time required in opening the circuit breaker. In the ordinary way the device will open in about 1/100th of a second if the excess current is heavy. This quickness of action makes the circuit breaker of much more use in certain instances than the ordinary fuse can possibly be, in that it interrupts the circuit before the excess current has had time to do damage to the various machines or mains of the circuit. We give in the



Laminated Edgewise Type of Circuit Breaker.

above illustration a typical form of one of these circuit breakers in order to show what are the essential parts, and the makers claim that this form has a distinct advantage over those at present in the market, where the circuit is interrupted by means of falling levers or weights. Here again the advantage lies in the quickness of action. When one comes to look through the list to see the enormous types and numbers of sizes of circuit breakers that are listed, the advantage of standardising will be at once recognised. These circuit breakers are all made to gauge, and can be ordered from stock. The sizes, however, are so exact that if they are to be mounted on a main switchboard, the holes in the slate which have to receive the parts can be drilled before the circuit breaker is delivered. Of course, the list contains circuit breakers for interrupting at overload or for the reverse currents, or even for both overload and reverse currents. There is, however, a new form which commends itself to electrical engineers, in which the circuit can actually be broken at the time it is made if the switch has been closed at the wrong instant. In other words, if a circuit breaker of this kind were used as a main switch, and the machine should accidentally become reversed, no harm would be done if the attendant in the switch-room tried to connect it in parallel with other machines, as the automatic circuit breaker would give relief even at the very instant it was being closed. In every case these circuit breakers have a certain range of adjustment by which they can be set for either overload or reverse current, which is a great advantage in central-station practice.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

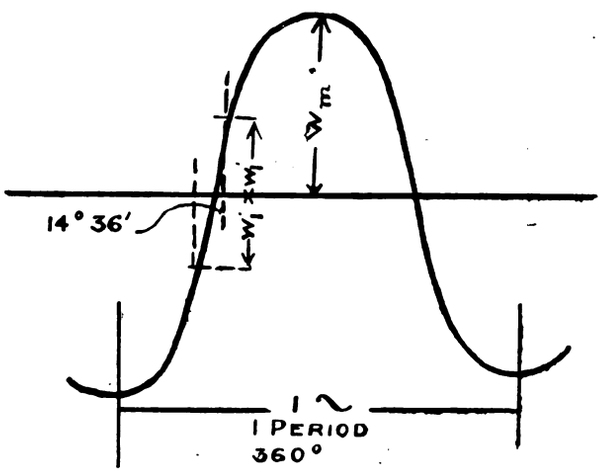
381. On a three-wire system, when the balancing set is shut down for repairs, and the remainder of the set is connected across the outers at 440 volts, and the motor-transformer is connected up for charging the regulation cells only, what would be the best method of charging-up the main battery?—W. M.

382. What is a paralleling voltmeter? How is it connected when used on a three-wire system, and is it a necessary instrument?—H. W.

ANSWERS.

Question No. 375.—Two 120-kw. and one 60-kw. alternators were running in parallel. The exciting circuit of the last named was broken, causing a dead short-circuit across the other two. The main switch on the 60-kw. set was opened and broke with a very small spark. Was this almost sparkless break due to the choking effect of the 60-kw. alternator armature, which was iron-cored? Working pressure, 2,100 volts.

Answer to No. 375 *(awarded 7s. 6d.).*—"R. W." may congratulate himself. If he had opened the switch a small fraction of a second earlier or later than he did, the switch, and probably the panel, would have had to have been renewed. The reason why the switch broke with so small a spark, was because it happened to be opened at the moment the watts were at zero, or nearly so; it could with a frequency of 80 be opened 100 times per second



with the same effect (the watt curve passes the zero line twice per period), but the time during which this may be done is very small. For instance, say the short was equal to 200,000 watts, the switch sparkless at 2,000 watts, frequency 80, then the sine of the angle during which the switch may be opened sparkless = sine = $\frac{W_1}{W} \frac{\sim}{2\pi}$

$= \frac{2,000 \times 80}{200,000 \times 2 \times 3{\cdot}14} = {\cdot}127$ angle = see table = 7° 18'.

This multiplied by 2 will equal the total angle during which the switch is sparkless = 7° 18' × 2 = 14° 36'. Time $= \frac{14° 36}{360 \times 80} = {\cdot}0005$ of a second; the total time during which the switch may be broken sparkless per second = ·0005 × 80 × 2 = ·08 of a second. "R. W." is also fortunate in having an iron-cored armature (60-kw. machine); otherwise the impedance to the impressed voltage would have been so small, that the current density would have risen to such a degree that it would have "busted up" his machine.—F. W. S. H.

Answer to No. 375 *(awarded 7s. 6d.).*—The smallness of the spark is due to the fact that as soon as the exciting

Digitized by Google

circuit was broken, the 60-kw. alternator immediately became transformed into an asynchronous alternating motor supplied by the two other alternators. It has long been known that when the circuit of a motor, whether continuous or alternating, is opened very much, less arcing occurs at the switch than when a circuit carrying the same current at the same voltage, but consisting of a dead resistance, such as incandescent lamps, is broken. The difference is especially noticeable when the motor armature has a large flywheel effect and is lightly loaded. The explanation is simple. When a current is broken at a switch, the amount of the sparking depends (neglecting inductive effects, which are practically absent in the present case) on the current which is still passing when the switch contact is opened to an appreciable extent. This current has to pass across the small air-gap thus formed as a visible arc. If by any means the current in the circuit can be reduced by the time the contact is broken, the sparking will be correspondingly reduced. Take the case of a continuous-current motor, and so avoid the complications introduced by change of phase relations in the alternating case.

Let E = the supply voltage (assumed constant at all currents);

e = the motor back voltage;

R = the motor armature resistance;

C and C_1 the currents in the circuit when the switch is closed and when it is just open respectively;

then $$C = \frac{E - e}{R}.$$

Now, during the fraction of time taken to open the switch, we may assume that the motor speed, and consequently e, will remain practically constant, due to the momentum of the armature, so that at the moment when the switch is sufficiently opened to introduce an additional resistance, r, into the circuit, the current will be $C_1 = \frac{E - e}{R + r}$.

In the case of a dead resistance load, R_1, supplied at E volts, and taking a current of C amperes, the two currents would be $C = \frac{E}{R_1}$ and $C_1 = \frac{E}{R_1 + r}$.

The great difference between the two cases will at once be seen by replacing the symbols by actual values. Let the motor be one supplied at E = 100 volts and taking 200 amperes = C. Such a motor would have an armature resistance of about ·02 ohm = R. Then $e = 100 - (200 \times ·02) = 96$ volts. When the switch is opened so as to add, say, only ·1 ohm to the circuit, the current will have fallen from C = 200 amperes to $C_1 = \frac{100 - 96}{·02 + ·1} = 33·3$ amperes. On the other hand, in the case of a dead resistance $C = 200 = \frac{100}{R_1}$. $\therefore R_1 = ·5$ ohm. When the switch is opened so as to add ·1 ohm to the circuit, the current will in this case have only fallen from C = 200 amperes to $C_1 = \frac{100}{·5 + ·1} = 166·6$ amperes. In fact, the presence of a motor has much the same effect on the sparking as reducing the supply voltage to a mere fraction (in this example to $\frac{1}{3}$) of its actual value.

Exactly the same explanation, slightly complicated by the impossibility of directly adding or subtracting voltages not in phase with one another, holds in the case of an alternating motor. In the case mentioned in the question, the motoring current passing through the 60-kw. armature would probably be from three to four times the full-load current of the machine, as that would be about the amount required by a modern iron-type alternator to induce a back voltage almost equal to the supply voltage by means of armature reaction alone. In spite of this largely increased current, however, the fact that the circuit contains a motor would be sufficient to reduce the sparking to a quite small amount. The fact that the armature is of the iron type has only an indirect effect on the sparking, by keeping the motoring current down to a smaller figure than would be the case with a coreless armature.—Q.

Answer to No. 375 *(awarded* 5*s.).*—The fact that the machines were iron-cored would undoubtedly moderate the strength of the current flowing into the unexcited machine, but it is not usual to find a 30-ampere machine whose self-induction is sufficiently great to choke down a dead short-circuit current to about 10 or 15 amperes (which would be the largest magnitude of the current to produce a very small spark under the most favourable circumstances) at full voltage. The further explanation is more probably to be found in the fact that, as the supply was alternating, there must have been instants when the voltage was actually at zero before passing on to the next phase. By great good luck the operator broke circuit at one of these instants. As there was only a trifling voltage at the moment of breaking circuit, it was possible to put an effective air resistance in the circuit before the pressure of the other alternators (assisted by the increased voltage due to the self-induction of the unexcited machine on breaking circuit) was sufficient to increase the spark into an arc. This may be seen more clearly by noting that unless there is absolutely no voltage on a circuit, there will be formed, at the instant the extreme edge of the switch blade leaves the tip of the jaws, a small spark, due to the heating and volatilising effect of the current passing through the high resistance of the point of contact. If there is induction in the circuit this spark will be increased, because, owing to the increased resistance of the circuit due to diminution of sectional area at the switch blade, an E.M.F. will be set up tending to strengthen the current up to or beyond its original strength. But in the case that we are considering we may suppose that the E.M.F. of the main supply was dropping down towards its zero position, thus tending to reduce the current in the circuit at the moment. On the other hand, the induction of the machine was producing an E.M.F. opposing that of the supply, and an instant would arrive at which the two opposing E.M.F.'s balanced each other. If the operator pulled out at this instant he probably saved himself an attack of ophthalmia. J. A. S.

Answer to No. 375 (*awarded* 5*s.*).—The fact that the armature of the 60-kw. alternator was iron-cored would certainly tend to reduce the magnitude of the short circuit current, but it is very improbable that the choking effect would be so great as suggested. One of the usual tests of a modern iron-cored armature is to run it on a short-circuit in its normal field, and when this is done the short-circuit current generally amounts to three to four times the normal working current of the machine (see Mr. Eborall's Society of Arts Howard Lectures, 1901). As this experiment should produce approximately the same current in the armature as placing it across the live terminals of a similar machine, it follows that the diminutive spark observed could not be attributed to the choking effect of the 60-kw. armature. It might be suggested that the spark was extinguished or suppressed by the capacity of the concentric mains or any other capacity which might have been connected as a shunt across the terminals of the alternators, but although Mr. W. Duddell showed very conclusively in his paper and experiments before the Institution of Electrical Engineers last year that a medium capacity as a shunt to the terminals of a metal switch prevents the formation of an arc when the latter is opened, it is not likely that such a large power could be suppressed in this way, especially as the capacity of the mains would not be acting as a direct shunt to the arc, but in series with the resistance and self-induction of the armature in question. The most reasonable explanation seems to be the result of a coincidence—namely, that the exact moment at which the switch was opened (and it is most likely that it was opened at a very high speed by the frightened attendant) coincided with the period at which the alternating current in the armature was zero. As explained above, the current was probably a very large one *on the average*, but being alternating there were, of course, two periods in each cycle at which it was nil, and it is probable that the switch was opened when the current was at zero, or had only a small positive or negative value. It has often been noticed when an alternating-current circuit is opened quickly that sometimes the spark is smaller than the average, and the explanation seems to be that mentioned above.—T. R. D. KENNY.

Question No. 376.—Discuss the advantages and disadvantages in the Lancashire and Galloway types of boilers of passing the flue gases first along the bottom of the boiler and then the sides, or *vice versâ*?

Answer to No. 376 (awarded 7s. 6d.).—There would seem to be very little to choose between the two methods of passing the flue gases; both are to be found in all parts of the country. Whatever difference there may be must be almost so small as not to be worth considering. In any case it is largely a matter of opinion; some engineers prefer one way, some another. Such advantages as either may claim can be stated as follows, the disadvantages of one being found in the advantages advanced for the other:

First along the Bottom and then along the Sides.—It is claimed by the advocates of this method that the gases, being at their hottest just as they leave the internal flues, will be able to impart considerable heat to a portion of the boiler (the bottom), in which the water is somewhat closely confined, and therefore the circulation will be improved in this part, and consequently there will be less chance for depositing mud. This portion of the boiler, moreover, receives no direct benefit from the fires, at least as regards the front part, which is immediately below the grate area, and therefore should properly receive the heat from the gases first.

First along the Sides and then along the Bottom.—In this method it is claimed that the gases being at their hottest, they can be utilised to better advantage by passing them first along the sides, as giving—approximately—say, twice the boiler-plate surface to absorb their heat over the former method. Having done so, they will now have less to part with, and can be again used to better advantage by giving them a smaller surface for the second journey. It may be also claimed for this method that the brickwork setting will be slightly cheaper, slightly simpler, and slightly stronger.

It will thus be seen how little there is to choose between the two methods. Such as they are, the advantages may, perhaps, be considered to rest with that in which the gases are first passed along the sides and then under the bottom. E. M. R.

Answer to No. 376 (awarded 7s. 6d.).—In looking at this question, we must remember that flame and heated gases always rise, and that, therefore, in passing through a tube or flue the hottest bodies, such as the flames, will always touch the top, consequently the hottest part of the flue will be the top. The lowest parts of the flue will be warmed by radiation only. The furnace is arranged with this fact in view, and water always lies on the top of the furnace in every kind of boiler. It is evident that the further the heated gases, etc., of the furnace go the more they become cool, and therefore we must make the best use of them as soon as possible. This is best done by putting them into contact with the coolest part of the water in the boiler; and we know that the coolest water is always at the bottom, therefore the bottom of the boiler is in a position to receive the most heat and to pass it on most advantageously to the water, because the heat of any part of the boiler itself never exceeds that of the water in contact with it, and a cold body can receive heat more rapidly and in greater quantity than a hot one. Therefore the heated gases and flames (if they are long enough, as they generally are) should be led from the furnace tubes underneath the boiler. This part of the flue should be made big enough to allow of ash and dust from the furnace settling there without being an obstruction to the draught, and it can now be divided, half going along one side of the boiler and half along the other, but the great disadvantage of this side flue is that the top of it and one side of it are only firebrick, and can therefore receive no heat usefully. However, the useful or boiler side of this flue is always curved (in section), and so it gets as much heat as possible under the circumstances. At the bottom of the inside of the boiler there is a large quantity of water ready to carry away heat it receives; but at the sides the water is hotter, there is not so great a volume, and it can more easily escape by reason of its position before it has received all the heat the furnace gases can communicate. This is not, however, in reality a loss, because other particles of water would quickly and continuously follow. The great disadvantage of the bottom or lower part of these boilers, is that the water at the bottom is necessarily cooled by being in contact with the bottom of the front part of the furnace flue, and this is cooled by the cold air going to the fire. This loss, however, occurs at the front end of the boiler, where the heating effect of the underneath flue is least because of the bifurcation to the side flues.

Another advantage of this arrangement—viz., passing the furnace gases underneath the boiler before going to the sides is that a greater and better circulation of the water is kept up inside the boiler, because at the back of the boiler where the flue turns down there is very great heat, so the water here rises rapidly from the bottom to the top, while at the front of the boiler—the coolest place—there is a downward flow. These convection currents are very useful, because they prevent the water from getting too quiescent, which is never advisable, and because they keep the quality of the water uniform. If the flue were led first round the sides and then underneath, the water might lie too quiet in the boiler, and the coolest water remain always at the bottom, while a considerable part of the heat of the furnace might be spent in warming the firebrick of the side flue to no useful purpose.

I therefore conclude that it is best to take the furnace gases underneath the boiler first and then along the sides, and I believe this is the most usual practice.—F. G. A.

COMPANIES' MEETINGS AND REPORTS.

KIDDERMINSTER AND DISTRICT ELECTRIC LIGHTING AND TRACTION.

Mr. J. S. Raworth presided at the ordinary meeting of the shareholders held at the London offices, and in moving the adoption of the report, already published in this journal, said that in August last the supply of electric energy for lighting and power was begun, and the actual number of lamps connected with the mains were now equivalent to 5,760 of 8 c.p., and applications for 186 more was now being dealt with. Some of the manufacturers had been induced to adopt motors for driving their machinery. New generating machinery was being laid down, which would increase the available power by 800 h.p. On electric lighting account alone they had lost something like £300, but it would be wiped out in the present year and a good dividend earned. Under the Kidderminster and Stourport Tramway head they had to their credit £54,439 for the purchase of the tramways and electrical equipment, and £1,278 on parliamentary deposits in consols; national war loan £591 at cost price. The reserve fund, which stood at £550, would be increased by another £500, the total balance of profit being £2,108. This, on the whole, he thought satisfactory. They had obtained a parliamentary order for a light railway to Bewdley, and it was hoped that its construction would be begun during the present year. He moved the adoption of the report and accounts.

Mr. R. P. Sellon seconded, and the motion was carried.

WEST INDIA AND PANAMA TELEGRAPH.

At the meeting of the shareholders, held at Winchester House, **Mr. W. S. Andrews**, the chairman, in moving the adoption of the report, said the receipts from messages and subsidies amounted to £24,600, or £1,656 more than in the corresponding half of the preceding year, while the expenses (£20,963) were £470 less, leaving a balance of only £3 337, which, together with interest on investments and £954 brought forward, made a total of £6,671, insufficient to meet the cumulative dividends on first and second preference shares for the half-year, amounting to £11,770. The directors thought it well to carry forward the balance. It was not the first time they had been in arrears with the preference dividend, but it had been made up. The ordinary shares had received dividends since 1890, taken partly from the appreciation of their securities, which was now at an end. They were all aware of the deplorable condition of our West India Islands. For years the Company's receipts had been decreasing, the period synchronising with the activity of Continental countries in the matter of bounties. The sugar industry was practically extinct, and no other could possibly take its place. The only hope for the West Indies was the imposition of countervailing duties or the abolition of the bounty system. This Company depended for its revenue on the prosperity of the islands, and unless something were speedily done he could not see his way out of the difficulty. The reduction in rates so far had not brought an adequate increase in messages.

Mr. H. Holmes having seconded the motion, it was carried.

ELECTRICAL POWER DISTRIBUTION.

Directors: Emile Garcke, M.I.E.E. (chairman); C. Shirreff Hilton; John S. Raworth, M.I.C.E.; R. Percy Sellon, M.I.E.E.; Wm. L. Madgen, M.I.E.E. (managing director). Secretary: Geo. J. Somerville.

Report of the directors (with abstract of accounts) to be

Digitized by Google

presented to the shareholders at the fourth ordinary general meeting of the Company to be held at Surrey House, Victoria-embankment, W.C., on Tuesday, June 4, 1901, at 12 noon :

The profits amount to £15,001. 2s. 9d., and, after deducting the proportion of general expenses chargeable to revenue, and the expenses incurred in connection with schemes not proceeded with and written off, and a sum of £1,271. 5s. 9d. held in reserve in respect of new schemes in course of development, there remains a net profit of £13,045. 11s. 2d., which the directors propose should be applied as follows: preliminary expenses written off, £826. 6s. 2d.; reduction of furniture account, £55. 15s. 2d.; payment of income tax, £513. 17s. 8d.; dividend at the rate of 5 per cent. per annum on ordinary shares for nine months or from the dates on which calls and instalments were paid, £1,320. 2s. 10d.—carried forward to next account, £10,329. 9s. 4d. The Company was incorporated on June 23, 1898, with a nominal capital of £20,200, divided into 2,000 ordinary shares of £10 each and 200 deferred shares of £1 each, and by special resolution dated April 19, 1900, the capital was increased to £300,000 by the creation of 12,980 ordinary shares of £10 each, and 15,000 preference shares of £10 each. The subscribed share capital is now £149,800 in ordinary shares of £10 each, and £200 in deferred shares of £1 each—total £150,000. There are at present unissued 15,000 preference shares of £10 each, which the directors propose to issue at an early date on terms to be announced. The total amount expended on Electric Power Acts and negotiations in connection with new schemes in course of development, less amount reserved, was £16,840. 13s. 6d., after writing off expenses incurred in respect of schemes not proceeded with, but including a portion of general expenses. The total expenditure under the head of investments was £31,730. 13s. The directors who retire this year are Mr. Emile Garcke and Mr. J. S. Raworth, and both are eligible for re-election. Mr. Ernest Wright, A.C.A., retires, and his firm, Messrs. Wright and Wake, offer themselves for election.

APPENDIX.

The attention of the Company has been particularly directed to economy in capital cost and administrative charges in connection with the electrical supply undertakings in which it is interested, and to developing the association with electrical traction and other allied interests so as to secure a comprehensive demand, a cheap and reliable supply to the public, and a satisfactory return upon the investment. The working agreement with the British Electric Traction Company, Limited, promises to be of much assistance in this direction, as it is enabling the electrical supply and the electrical traction undertakings in the same districts to be worked together to mutual advantage, and under the most favourable conditions in regard to operating expenses. The extent of country over which electrical energy can be the most cheaply distributed, and over which improved traffic facilities can be given by means of electrical traction, has largely increased during recent years. There are indications that comprehensive undertakings combining these services will equal in importance some of the largest national industries, and that the arrangements most satisfactory to the public are as little susceptible of local treatment within arbitrary boundaries as are the railway or telegraph systems of the country. The business undertaken by this Company in association with the British Electric Traction Company is directly in this line of development, and it is believed that the positions which the Company has secured will enable it to show satisfactory results from year to year while making those extensions which circumstances render desirable. The following are concise particulars of undertakings now in hand:

Banbury.—The Electrical Power Distribution Company has obtained the Banbury electric lighting provisional order intended to be transferred to the Banbury and District Electric Supply Company, Limited, which has been formed for the purpose of carrying out the undertaking. Present subscribed capital, £25,000.

County of Durham.—The County of Durham Electric Power Distribution Company, Limited, has been formed with a capital at present subscribed of £30,070, for the purpose of carrying out electrical supply undertakings in that county. Provisional orders under the Electric Lighting Acts, authorising retail supply to consumers for power, light, and other purposes, have been obtained for Gateshead, Jarrow, and Durham (City). Satisfactory progress has been made with the work, and it is expected that general supply will be commenced during the present year in Gateshead about Aug. 1, in Durham (City) about September, and in Jarrow about November. With a view to facilitating the operations of the above company, and those of the British Electric Traction Company, Limited, in the same area, the Electrical Power Distribution Company, in the last session of Parliament obtained an Electric Power Act, under the title of the County of Durham Electric Power Supply Act, 1900, by means of which electrical energy can be supplied in bulk under favourable conditions to retail undertakings, such as those above mentioned, to electric tramways and light railways, and to other authorised users for prescribed purposes within an area of about 250 square miles, bordering on the south side of the River Tyne, and comprising a large portion of the engineering and colliery districts of the county. The construction of the main power station at Gateshead has kept pace with the equipment of the local sections of the traction scheme for the county to which it is supplying current, and both of these undertakings have been successfully inaugurated this month.

County of Kent.—The Electrical Power Distribution Company has obtained the Sheerness Electric Lighting Provisional Order, 1900, and the Sevenoaks Electric Lighting Provisional Order, 1900, and it is intended to transfer these orders to the County of Kent Electrical Power Distribution Company, which has been formed with a capital at present subscribed of £25,000, for the purpose of carrying out such undertakings in the county. The British Electric Traction Company, Limited, is promoting a light railway order for Sheerness, which has been passed by the Commissioners, and it is intended that this line, when authorised and equipped, shall be worked in conjunction with the electric supply undertaking.

County of Northampton.—The Wellingborough electric lighting provisional order has been obtained by the Electrical Power Distribution Company, and it is intended to transfer it to the County of Northampton Electric Power and Traction Company, Limited, which has been formed with a capital at present subscribed of £25,000 to carry out this and other electrical undertakings in the county. The British Electric Traction Company, Limited, has obtained an Act authorising the construction of an electric tramroad system in Wellingborough, Rushden, and neighbouring districts, and with a view to economy in administration it is in contemplation to work the undertakings conjointly.

County of Surrey.—The County of Surrey Electrical Power Distribution Company, Limited, has been formed, with a capital at present subscribed of £25,070, and provisional orders under the Electric Lighting Acts have been obtained for the neighbouring districts of Sutton, Carshalton, and Wallington. It is expected that the supply will be commenced during the present year.

County of Sussex.—The provisional order under the Electric Lighting Acts for the borough of Lewes has been obtained for the County of Sussex Electrical Power Distribution Company, Limited, which has at present a subscribed capital of £20,070. The works are on the point of completion, and supply will commence next month.

North Metropolitan District.—The North Metropolitan Electrical Power Distribution Company, Limited, has been formed, with a capital at present subscribed of £25,070, for the purpose of carrying out electrical supply undertakings in this important district. Provisional orders under the Electric Lighting Acts authorising retail supply have been obtained for Barnet and Hertford, and negotiations are proceeding with other districts. In Barnet the supply was commenced in September of last year. In Hertford the undertaking is well advanced, and the supply will be ready for the autumn of the present year. With a view to the supply of electrical energy in the North Metropolitan districts under comprehensive and economical conditions, the Electrical Power Distribution Company in the last session of Parliament applied for and was granted the North Metropolitan Electric Power Supply Act, 1900, authorising the supply of electrical energy, under conditions similar to those of the County of Durham Act, within an area of about 325 square miles, including the great suburbs to the north of London, from Tottenham on the east to Harrow on the west, and the growing manufacturing districts along the River Lea. It covers the area within which the extensive North Metropolitan electric light railways are being promoted by the British Electric Traction Company, Limited, and allied interests.

Digitized by Google

Penarth.—The Penarth Electric Lighting Company, Limited, with a present subscribed capital of £25,000, has the provisional order under the Electric Lighting Acts for Penarth, a growing residential district and seaside resort adjoining Cardiff. The works are in course of construction and the supply is expected to commence in the coming month.

Staines, Egham, and Chertsey.—The Electrical Power Distribution Company has obtained a provisional order under the Electric Lighting Acts for the neighbouring districts of Staines, Egham, and Chertsey, and it is intended to transfer it to the Thames Valley Electric Supply Company, Limited, which has been formed with a capital at present subscribed of £25,000 to carry out the undertaking.

Weston-super-Mare.—A provisional order under the Electric Lighting Acts has been obtained by the Weston-super-Mare and District Supply Company, Limited, which was formed for the purpose of carrying out the undertaking, and has a capital at present subscribed of £25,070. The works are now on the point of completion, and supply will be commenced immediately. In addition to the concession for the electrical supply, the Company has also obtained a provisional order for a system of electric tramways in the town, and with a view to producing the most satisfactory results it is intended that the two undertakings shall be worked together.

There are other provisional arrangements which have been made, and negotiations are pending in regard to a number of other undertakings, but it would be premature and inexpedient to describe them at this stage.

MEXICO ELECTRIC TRAMWAYS.

With the report of the directors of the Mexico Electric Tramways, Limited, for 1900 the accounts of the Compania de Ferrocarriles del Distrito Federal de Mexico, S.A., for the same period are given, the dollar being taken as equivalent to 2s., with a view to demonstrating the position approximately in British currency. The net balance to the credit of the profit and loss account at the close of the year was £26,966, which enabled the Board in Mexico to declare a dividend of 12½ per cent. on the ordinary share capital. This dividend, together with the interest received, has been duly credited to the revenue account of the Mexico Electric Tramways, Limited, which shows a credit balance of £24,545. A dividend of 6 per cent. on the preference shares has been declared, which will absorb £5,564, leaving a balance in hand of £18,980. The directors recommend a dividend of 5 per cent., amounting to £15,000, on the ordinary shares, leaving a balance of £5,980 to be carried forward. The past year's results have been materially prejudiced by the dislocation of traffic, due to the reconstruction of the system, and by the congestion caused by the introduction of an entirely new drainage system throughout the city. The country has, moreover, passed through a year of commercial depression.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Glasgow.—The Corporation invite tenders for the supply of electricity meters. Tenders by June 10. Details in our advertisement columns.

Rochdale.—The Corporation invite tenders for six specimen electric tramcars. Tenders by June 7. Details in our advertisement columns.

Islington.—The Lighting Committee invite tenders for free or assisted wiring. Tenders by June 11. Details in our advertisement columns.

Glasgow.—The Corporation invite tenders for the supply of branch rubber-covered cables. Tenders by June 10. Details in advertisement columns.

Edinburgh.—The Corporation invite tenders for ash-conveying plant, Dewar-place station. Tenders by June 15. Details in our advertisement columns.

Dundee.—The Town Council invite tenders for the overhead equipment of Seagate route. Tenders by June 5. Details in our advertisement columns.

Hendon.—The Urban District Council invite tenders for the wiring of the new Council offices. Tenders by June 5. Details in our advertisement columns.

West Stanley (Durham).—Tenders for electric lighting are invited on inspection for new Catholic church, West Stanley. Apply to Rev. J. Thompson. Tenders by June 1

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection of dry-back marine-type boilers. Tenders by June 8. Details in our advertisement columns.

Farnworth.—The Urban District Council invite tenders for the overhead equipment of about five miles of tramways and tramway poles. Tenders by June 7. Details in our advertisement columns.

Manchester.—The Tramways Committee invite tenders for the supply of electrical fittings for the lighting of their Queen's-road car-shed. Tenders by June 4. Details in our advertisement columns.

Huddersfield. — The Corporation invite tenders for five mechanical stokers, to be fixed to five 8ft. by 30ft. Lancashire boilers. Tenders by June 4. Details in our advertisement columns.

London, E.C.—The East Indian Railway Company invite tenders for electric overhead travelling cranes, etc. Specification may be seen at the Company's Offices, Nicholas-lane, London, E.C. Tenders by June 12.

Dublin.—The Lighting Committee invite tenders for the supply and erection of motors and motor-generators, accumulators, meters, and works wiring. Tenders by June 3. Details in our advertisement columns.

Islington.—The Lighting Committee invite tenders for the painting of the arc lamp columns and crutches, of which 398 are in use in the borough. Tenders by June 11. Details in our advertisement columns.

Peterborough.—The Corporation invite tenders for the supply and erection of one Lancashire boiler, 30ft. by 8ft., and one 120-kw. steam dynamo. Tenders by June 14. Details in our advertisement columns.

Colmenar Viejo.—Tenders are invited for installation and working for 20 years of electric lighting. The public lighting will require 150 16-c.p. lamps. Tenders to the Mayor of Colmenar Viejo, Province of Madrid, Spain.

Dublin.—The Lighting Committee invite tenders for the supply and erection of main switchboards, sub-station switchboards, transformers, arc lamps, and arc lamp pillars. Tenders by June 3. Details in our advertisement columns.

Exeter.—The Town Council invite tenders for erection of the buildings of their new electricity generating station. Specifications, etc., may be obtained from Mr. Donald Cameron, city engineer and surveyor. Tenders by June 14.

Salford.—The Corporation invite tenders for the supply and delivery of additional steel poles, cast-iron bases, etc. (Contract No. 16), in connection with the electric tramways. Tenders by June 3. Details in our advertisement columns.

Uxbridge.—The Uxbridge and District Electric Supply Company invite tenders for erection of a generating station on land adjoining the Waterloo-road. Specifications, etc., can be obtained from the Secretary's Office, 1, Vine-street. Tenders by June 4.

Aldershot.—The Urban District Council invite tenders for erection of buildings and shaft in connection with their electric lighting station. Specifications, etc., may be obtained from Mr. Nelson F. Dennis, A.M.I.C.E., surveyor. Tenders by June 4.

Edinburgh.—The Corporation invite tenders for the electric lighting installation, etc., of the first portion of the Colinton Mains Fever Hospital, the number of lighting points being about 1,550. Tenders by June 12. Details in our advertisement columns.

Exeter.—The Council invite tenders for boiler-house equipment, pipes, etc., engine-room equipment, switchboards, connecting cables, coal bunkers and conveyors, and feed and condensing water tanks. Tenders by June 14. Details in our advertisement columns.

Wakefield.—The Corporation invite tenders for supplying and fixing a new armature to a steam alternator at the electricity works, Calder Vale, Wakefield. Specifications, etc., may be obtained on application to the City Electrical Engineer, at the Electricity Works. Tenders by June 4.

Doncaster.—The Corporation invite tenders for steel grooved girder tramway rails for eight miles of tramways in the borough of Doncaster and adjoining neighbourhood. Particulars may be obtained at the office of the borough surveyor, Mr. W. H. R. Crabtree, M.I.C.E., 3, Priory-place, Doncaster. Tenders by June 3.

Taunton.—The Corporation invite tenders for the construction, supply, and erection of one 250-kw. steam alternator, one 15-kw. motor-generator, switchboard extensions, one water-tube boiler, superheater, jet condenser, and air-pump, and sundry pipe extensions. Tenders by June 11. Details in our advertisement columns.

Burnley.—The Electricity Committee invite tenders for (A) five injectors, capable of dealing with 700 gallons per hour; (B) one feed pump, capable of dealing with 3,500 gallons per hour. Specifications, etc., may be obtained on application to Mr. Robt. Birkett, the borough electrical engineer, Aqueduct-street, Burnley. Tenders by June 10.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

York.—The North-Eastern Railway Company invite tenders for the following articles, in such quantities as they may require, during six months ending Dec. 31, 1901, delivered carriage paid at the telegraph stores at York: (1) telegraph apparatus; (2) telegraph wire and line stores. Particulars may be obtained on application to Mr. Graves, Telegraph Department, York. Tenders by June 10.

Dundee.—The Town Council invite tenders for steel fishbolts, with locknuts (about 186cwt.); steel tie-bars with nuts and washers (about 864cwt.; steel joint plates, with bolts and lock nuts (about 2 600 sets); and cast-steel points and crossings (about 435cwt). Specification, etc., may be obtained from Mr. W. Mackison, C.E., Municipal Offices, 91, Commercial-street, Dundee. Tenders by June 4.

Kearsley.—The Urban District Council invite tenders for the taking-up roadway and repaving, laying of rails, points, etc., and all labour required for the construction and completion of

Digitized by Google

tramways from Market-street to Unity Brook and along Long-causeway at Kearsley. Specifications, etc., may be seen at the office of the Council's surveyor, Mr. Herbert Nuttall, A.M.I.C.E., 20, Market-street, Bury. Tenders by June 13.

London, S.W.—Tenders are invited for the supply of 13,400 tons of steel rails and 958 tons of fishplates for the Queensland Railways. Tenders will be received at the Queensland Government Office, 1, Victoria-street, London, S.W., until 2 p.m. on June 11, endorsed "Tender for Steel Rails and Fishplates," and accompanied by a preliminary deposit of 1 per cent. on the tender. Specifications, drawings, etc., may be obtained at the office of the Agent-General for Queensland.

Warrington.—The Corporation invite tenders for the supply, delivery, and erection of one water-tube boiler and pipework; supply, delivery, and erection of 500-kw. high-speed engine of the Willans type, with direct-coupled continuous dynamo; and supply, delivery, and laying of underground mains, stoneware conduits, etc. Specifications, etc., can be obtained at the offices of Messrs. Preece and Cardew, 13, Queen Anne's-gate, Westminster, S.W. Tenders by June 13.

Uganda.—The Crown Agents for the Colonies, acting on behalf of the Uganda Railway Committee, invite tenders for the supply of galvanised iron wire, specification and form of tender for which can be obtained on application to the Crown Agents, at whose office the drawing will be on view between the hours of 10 a.m. and 4 p.m. (Saturday, 10 to 2). Tenders to be delivered, addressed to the Crown Agents for the Colonies, Downing-street, S.W., and endorsed "Tender for Galvanised Iron Wire, Uganda Railway," not later than noon on June 11.

RESULTS OF TENDERS.

Manchester.—The Corporation have accepted the tender of the Electrical Company, Limited, 122-124, Charing Cross-road, W.C., for six three-phase generators of 2,500 h.p. each, and for sub-station motor-transformers.

Royal Yacht.—We learn from the General Electric Company that they have received an order from Messrs. Waring and Son, of Hammersmith, for special "Robertson" lamps for the King's dining saloon on the new royal yacht.

Stoke-upon-Trent.—The Guardians have accepted the tender of F. W. Smith and Co., Southport, at £401, for electric motors for driving new laundry machinery, also the wiring of laundry buildings, nurses' home, and farm buildings. Twenty tenders were received.

Brighton.—The Corporation have accepted the tender of Messrs. Redpath, Brown, and Co., Limited, of Edinburgh, at £15,978, for the erection of the iron and steel work required in the construction of an electrical power station at Southwick. Thirty-nine tenders were received, ranging from £15,909 to £52,500.

Todmorden.—The Fielden Joint Hospital Committee have accepted the tender of R. S. Blackburn, Hebden Bridge, for the erection and maintenance of telephonic communication between the Fielden joint hospital, the workhouse, and the Urban District Council offices at Hebden Bridge, and the Urban District Council offices at Mytholmroyd, and the house of the receiving officer at Hebden Bridge.

Poplar.—The Borough Council have accepted the tender of Mather and Platt, Limited, for the supply of 500-kw. generator, balancer, generator and booster, spare armature and switch gear, in accordance with specification, at £10,371; also the tender of Babcock and Wilcox, Limited, for the supply of two boilers, two chain-grate stokers, two superheaters, Green's economiser, water softener, and extension of coal bunkers, in accordance with specification, at £4,482.

Fulham.—The following tenders have been recommended for acceptance: Boult Bros., engine oils, £135. 9s.; J. Gibb and Co., asbestos packing, £57. 15s.; General Electric Company, incandescent lamps £43. 4s., arc lamps and accessories £147. 15s. 10d., fuse wire, tape, etc., £33. 3s. 2d.; City Glass Company, arc lamps, globes, etc., £13. 8s. 6d.; De Grelle, Houdret, and Co., carbons £45. 8s. 3d.; Electric and General Contracting Company, service boxes £635. 12s. 6d., compound £13. 2s. 6d.; Johnson and Phillips, cables, tents, etc., £381. 14s. 3d.

BUSINESS NOTES.

TRACTION.

Oldham.—Major Druitt, R.E., on behalf of the Board of Trade, has inspected two sections of the electric tramways.

Twickenham.—The District Council have dropped their opposition to the London United Tramways Bill upon terms.

Blackpool.—Major Druitt, Board of Trade inspector, has inspected the extension of the Corporation's tramways to Marton.

Hull.—On Whit Monday the traffic receipts from the Corporation tramways amounted to £465, as compared with £383 the corresponding day last year.

Brentford.—At the last meeting of the Town Council it was stated that it was the intention of the tramway company to commence running trams on July 1.

Ramsgate.—Another portion of the Isle of Thanet electric tramways was opened on Wednesday for traffic from the harbour along the West Cliff to Ellington Park.

Llanelly.—The tramway company have submitted their scheme for electric tramways to the Board of Trade, and a definite answer is expected within the next three or four days.

Middlesex.—The County Council have adopted the report of their Parliamentary Committee, slightly amended, in favour of the scheme of tramways from Tottenham to Staines.

Southampton.—The Board of Trade have sanctioned the proposed tramways loan of £80,000—£53,820 for permanent way, £7,230 for electrical equipment, and £18,950 for cars.

Wolverhampton.—The Town Council on Friday confirmed their resolution in committee with reference to the adoption of the Brown surface-contact system of traction for the tramways.

Bradford.—The work in connection with laying down the tramway from Bradford to Queensbury is now nearing completion, and it is thought the cars will be running to Queensbury next month.

King's Norton and Northfield Tramways.—The opposition to this Bill having been withdrawn, it has been referred to the consideration of the Committee on Unopposed Bills in the House of Commons.

Portsmouth.—It is anticipated that the consent of the Local Government Board to the borrowing of £600,000 for the purchase of the new electric trams in the town by the Corporation will be received within the next week or so.

Halifax.—It is noted with satisfaction that the receipts of the Northowram tramways have recently compared favourably with those taken on other routes. The takings on the section during the fine weather amounted to about 11½d. per car mile.

Ramsgate.—The Town Council having come to the conclusion that the explanation of the Isle of Thanet Electric Tramway Company with reference to the recent accidents on their system is not satisfactory, have decided to appeal to the Board of Trade.

Leeds.—The electric launch which was recently placed on the Waterloo Lake, Roundhay Park, by the Corporation was tested by Mr. John McEwan, Board of Trade surveyor, on Friday, and on Saturday the certificate of the Board of Trade was received.

Darlington.—The municipalisation of the tramways was considered at a General Purposes Committee meeting, when a motion that a special meeting of the Council be called to consider the purchase of the tramway system for £7,500 was ultimately carried.

Manchester.—Lieut.-Colonel von Donop, Board of Trade inspector, has inspected the permanent way of the Cheetham Hill route of the new municipal electric tramways system. Mr. Trotter inspected the electrical equipment. It has been definitely arranged that the electric tramcar service shall begin on June 6.

Wigan.—Tenders are to be obtained for rails, fishplates, other ironwork, setts, gravel broken stone, and cement for the proposed extension of tramways. The borough engineer has been instructed to complete the Martland Mill Bridge route, and separate tenders are to be obtained for the rails, etc., required for the work.

Merthyr Tydvil.—The Cabs Committee have received a reply from the Board of Trade to the effect that it was unable to delay the settlement of the proposed regulations for the electric railway until the 5th prox., and that the line would not be inspected by the Department unless there was some special reason for doing so.

Hammersmith.—At the fortnightly meeting of the Borough Council the clerk presented a letter from the tramways company, stating that the use of the gongs for the avoidance of danger had been approved by the Board of Trade, and the rate of speed in travel is in conformity with the regulations framed in connection therewith.

Aberdeen.—The Tramways Committee have approved a scheme of greatly extending the car service in the city. A letter has been received from the Board of Trade stating that they would not allow guard slips to be put up in connection with electric tramways, and that guard wires were necessary. Guard wires, it was explained, had been in use in Aberdeen for some time.

Bristol.—The cars run on Whit Monday last year numbered 120 and the passengers carried 154,628. On Monday last the cars run numbered 216 and the passengers carried 248,909, showing an increase of 94,281 over last year. This year the whole of the cars run are worked by electricity, whereas on the Bank Holiday of last year many of the cars were worked by horse power.

Paris-Bordeaux Automobile Race.—There were 90 entries for the motorcar racing contest between Paris and Bordeaux, England being represented by one 70-h.p. Napier car. The victory was accorded to Mr. Fournier, who rode a Morse machine, and who accomplished the journey of over 370 miles in 8 hours, 44 minutes, and 45 seconds. He thus maintained an average speed of five miles every eight minutes.

Newcastle.—A joint meeting of the sub-committee of the Tramways and Markets Committees has been held to reconsider the application from the Tramways Committee to acquire part of the pig market for car-sheds. The question of erecting car-sheds over the pig market, by means of a lift, was under consideration, and other plans were also discussed. The meeting stood adjourned for the Tramways Committee to submit a definite plan of their requirements.

Crewe.—The British Electric Traction Company some time ago sought and obtained from the Light Railway Commissioners an order to construct light railways in Crewe, but owing to the impracticable conditions imposed by the Corporation, the order was allowed to lapse. Last year the Corporation applied for a

Digitized by Google

similar order for themselves. The London and North-Western Railway opposed, and the order was refused. On Saturday the Electric Traction Company gave notice of application for another order for Crewe.

Birstall.—It is understood that the District Council are in negotiation with the British Electric Traction Company with regard to that section of the tramlines which passes through the Council's district, and that in the course of a few days the result will be made known. With respect to the portion between Birstall and Gomersal notice to acquire has already been served on the tramways company, and similar notice will be given in August in relation to the small length of line between Smithies and the foundry at the junction of the cross-roads.

Sunderland.—It is stated that the Corporation tramways carried over 100,000 passengers on Whit Monday. This is a record for the town, the previous highest being 60,000 on Easter Monday. The first extension made upon the original scheme of tramways—that reaching from Roker-terrace to Sea-lane—has been inspected by Lieut.-Colonel von Donop, inspector to the Board of Trade. The section is about three quarters of a mile long, and, being an almost absolutely straight line and devoid of any serious gradient, does not present any special structural difficulties.

Lancaster.—At the last meeting of the Town Council the Tramways Committee reported that they had had an offer from a syndicate to purchase the right to construct electrical tramways in the borough, obtained from Parliament last year. The idea of the syndicate was to buy the tramway system between Lancaster and Morecambe, convert it to electrical traction, and then connect it with the proposed Lancaster route. The committee had refused the offer, and the Council confirmed the decision. A beginning with the actual work of laying down the new system in the borough would be made soon.

Pontefract.—A Bill has been introduced into the House of Lords by Lord Dudley, Under-Secretary of the Board of Trade, to confirm a provisional order authorising the United Kingdom Tramway Syndicate to construct tramways in the borough of Pontefract, the urban districts of Castleford, Featherstone, Normanton, and Whitwood, and the rural district of Pontefract, all in the county of the West Riding, York, and for other purposes. The order sets forth 20 sections of the tramway, and it is provided that the promoters shall cause an electric lamp of not less than 16 c.p. to be erected on the posts at every interior angle of the road of 120deg. or less, and at every stopping place on the said tramways.

Newport (Mon.).—A town's meeting has been held to consider the question of the proposed conversion of the tramways to electric traction. The Town Clerk said the amount involved in the Parliamentary Bill was divided—£90,000 for tramways, with extensions, and £40,000 for electrical purposes. The Mayor explained that at the last meeting of the Town Council tenders for electric traction and power station amounting to £50,000 were accepted. The whole scheme would cost £96,000. Eventually, a resolution that the Mayor and Corporation be asked to rescind the resolution carried at the last meeting of the Council was carried by a large majority. It is expected that a poll of the ratepayers will follow this action.

Metropolitan Railway Bill.—The Parliamentary Committee appointed to consider this Bill has issued a special report, in which they say that it is intended by the Bill to empower the Metropolitan Railway Company and the Harrow and Uxbridge Railway Company to make a deviation railway and other works, and to abandon portions of authorised railways which will be thereby rendered unnecessary, and to release a portion of the money deposited with the High Court of Chancery in respect of the abandoned portions of railway; and that it is proposed by the Bill to revise and extend the period limited by former Acts for the compulsory purchase of lands and for the completion of the railways and other works thereby authorised.

Sheffield.—On Saturday night a fitter's labourer named Joseph Hand was knocked down and killed by an electric car which ran right over him. It was some 20 minutes before his body was recovered from beneath the car, and at the inquest on Tuesday the question of the delay in extricating the body was raised. The jury returned a verdict of accidental death, the foreman remarking that he thought it would be wise for the Corporation to provide some means of lifting cars without such delay. If a man's foot had been under the car there would have been a similar delay, there being no appliances on the car. It was finally agreed to add a recommendation from the jury, to the effect that "jacks" should be stationed at frequent intervals along each tramway route.

Glasgow.—On behalf of the Board of Trade, Colonel Yorke has inspected the permanent way of the electric tramway routes between St. Vincent-place and Maryhill and St. Vincent-place and Kelvinside. The electric cars are expected to be running on these routes in the course of a few days, after which the horse car traffic will practically be confined to the southern and eastern districts of the city, in which, however, the electric cars are already partially in operation. The total receipts of the Corporation tramways for the year ending this week amount to £485 000, as against £464,786 for the previous year, giving an increase of over £20 000. Of that increase about half is accounted for since the exhibition opened and the electric cars began to run, the increase at the end of April being about £10,000.

West Ham.—The idea of enlarging the present power station at Abbey Mills in connection with the proposed tramways has been abandoned in favour of erecting entirely new premises on the site of the old sewage pumping station at Canning Town. The equipment of the new station will comprise three sets of engines and dynamos, with a total capacity of 1,500 kw. for tramway purposes; seven sets, with a capacity of 4,800 kw. for lighting and other purposes; 16 boilers, five condensers, two economisers, and accessories. Altogether the new station will possess a capacity of 4,800 kw. The electrical engineer (Mr. James K. Bock) in his report, submitted to the Council, on the power to be installed for tramways, suggests that it would be well to provide sufficient power to supply 100 motorcars at one time.

West Cumberland Tramways Bill.—The House of Commons Select Committee presided over by Mr. Seale Hayne has passed the preamble of this Bill, the only opposition before the committee coming from Cleator Moor. Under this Bill it is proposed to raise £400,000 by shares and £100,000 by borrowing for the purpose of constructing tramways and to supply electricity for all public and private purposes within certain limits. The proposed tramway commences at Cleator Moor, runs through Whitehaven to Workington, Low Seaton, Maryport, and terminates at Silloth, being 31 miles in length. The line would serve 15 important villages and five important towns, the latter having a population of 68,000, and the whole district 120,000. The estimated cost of the line and generating station is £361,000. With respect to the opposition of Cleator Moor, their only real objection was in respect of a bridge, which they said the promoters should be compelled to widen if they were making their tramway, but the committee decided that the bridge in question was wide enough for the purpose.

Warrington.—At the monthly meeting of the Rural District Council the promoters of the South Lancashire tramways scheme wrote stating that they are now in a position to agree to undertake the supply of electricity in bulk to the Council for the purpose of electric lighting, power, etc., in the district of Burtonwood. The proposals of the company, briefly, are that the Council should obtain their own electric lighting order and provide a network of distributing mains in the district named, together with the sub-station for receiving the supply of electricity in bulk. The Council would thus become their own undertakers under the Electric Lighting Act, and would by this arrangement be relieved from a large capital outlay for a generating station. The company's generating station would be situate at Atherton, and mains would be laid to the district free of charge. It was stated that the opinion at Burtonwood was that they would rather carry the electric lighting scheme out themselves, and it was decided that the matter should be in abeyance pending a further expression of opinion from Burtonwood on the subject.

Cardiff.—At a meeting of the Tramways Committee on Friday the sub-committee reported in detail on their inspection of different types of electric cars in different parts of the country. The sub-committee stated that owing to the exceptional features arising both in the service required and on some of the routes over which the cars would have to work at least three types would be necessary—single deck bogie cars, double deck bogie cars, and double deck four-wheel cars. The committee recommended that the Splott route should terminate at Custom House-street instead of running the single deck cars through to Grangetown, where double-deck cars could be very easily used. The single-deck car recommended would have a carrying capacity of 31 passengers, and the double-deck bogie cars a carrying capacity of 68 passengers, having accommodation for 30 passengers inside and 38 outside. Lath garden seats instead of the knifeboard or longitudinal seats, a double staircase, and two motors as propelling power were also recommended. The recommendations were adopted, and the engineer was instructed to prepare specifications, so that tenders might be invited as soon as possible.

Blackburn.—As stated in our last issue, the annual report on the working of the Corporation tramways, as presented to the Tramways Committee, shows a loss of £3,776 on the year's working. The total receipts from both electric and steam traction amount to £36,972 odd, while the working expenses amount to £28,947 odd, leaving a balance of £8 024 odd. Taking into account the capital charges on loans to the figure of £11,801 odd, there is a deficit of £3 776 odd. Throughout the past year the work of the electric equipment of the lines and the relaying of the permanent way have been pushed on as fast as material could be delivered, and it is anticipated that the cemetery section will be ready for electric traction by the end of June and the Church section by the end of July. In October last the Darwen section was opened for electric traction, and has worked satisfactorily, and shown a considerable increase in receipts over the corresponding period of the previous year. Referring to the financial position, the report states that the electric car expenses are higher than what they will be when all the sections are working, on account of sundry expenses incurred in handling the new cars as they are delivered, and this amount can only be placed against the revenue. The receipts per mile on all sections are not as high as was expected, partly owing to the large amount of mileage run in the early hours of the morning for experiment. An increase of fares is, therefore, recommended. There are at the present time 5·22 miles of electric tramways in operation and 5·5 miles of steam.

Belgium.—The sixteenth annual report has been issued of the Société Nationale des Chemins de Fer Vicinaux, which was founded in 1884, under the auspices of the Belgian Government, for endowing with railways, generally light, and of metre (3ft. 3⅜in.) gauge, districts which would not in the ordinary way receive the benefits of railway communication for many a year to come; but, through the beneficent action of the society, the railways are made and stocked by means of capital subscribed,

Digitized by Google

in varying but defined proportions, by the Government, the provinces, the communes through which they pass, and companies or individuals interested in them. Although a few lines in outlying districts did not pay their way at first, and some of them even incurred a considerable loss, provided for by general and special reserve funds, such loss is now almost entirely made good, and only two of the 104 lines conceded, representing a collective length of 1,481 miles, show a slight balance on the wrong side. To the report is appended a graphic diagram showing at a glance the progress of the society's operations since its formation, with the remarkable success achieved. After the first year's working the curve of the annual receipts is almost a straight line, the figure having increased from £3,505 in 1885 to £393,660 last year. The curve of the lengths worked, also varying but slightly from a straight line, shows an increase from 36 miles in 1885 to 1,143 miles last year. The curve of the lengths of lines conceded shows greater variation, as also does that of the capital subscribed, for each line has its separate capital, attaining last year the total of £4,964,360. Of the 79 lines that have been worked for more than a year, 40 yield a dividend higher than that guaranteed; 10 more than 3 per cent.; 11 more than 2½ per cent.; and six more than 2 per cent.

London Underground Railways.—The Joint Committee of the two Houses of Parliament appointed to consider the routes proposed in various underground railway Bills now before Parliament resumed their enquiry on Friday. On behalf of inhabitants of Hampstead, counsel removed an impression that there was no opposition to the Charing Cross, Euston, and Hampstead line. Mr. Balfour Browne, K.C., opened the case for the King's-road Railway. From Eel Brook-common at Fulham the line would proceed through a densely-populated district, of which King's-road was the main artery, and would terminate at Victoria Station, where the line would get into touch with more than half the railways of London. It was stated in evidence that the line would be two miles and six furlongs, and there would be stations at Wandsworth Bridge-road, Grosvenor-street, and the bottom of Sloane-street. The size of the proposed tube was 11ft. 6in., and there would be two classes of fares at a uniform rate. Mr. Balfour Browne next stated the case for the Piccadilly and City line, which, starting from an end-on junction with the North-Eastern London line at Cannon-street and interchanging traffic there with the District Railway, would proceed, with stations at Ludgate-circus, the Law Courts, and Wellington-street, Strand, to Charing Cross, and finally to Piccadilly, where it was proposed to make an end-on junction with the Piccadilly and Brompton line. If, however, the promoters of the latter line objected to this junction, then by means of an interchange station the Piccadilly and City passengers could have connection with the Hammersmith and Charing Cross line. Sir Douglas Fox described the route with its various connections and subways, and pointed out how St. Paul's Cathedral had been carefully avoided by taking the line under Carter-lane. The congested space in front of the Mansion House had also been avoided. The tube contemplated would be 13ft., but the promoters proposed powers for 13ft. 6in. Counsel then opened the case for the West and South London Junction line. The sections of the line proposed include a line from Bishop's-road, Paddington, to the Marble Arch. Another section would continue the line to Victoria, arrangements having been made with the Office of Woods and Forests to run under the park by the side of Park-lane. A third section passed from Victoria under Vauxhall Bridge-road to the river, and thence by the Oval to a terminus in Camberwell New-road, where a generating station would be established. Subways at various points would give passengers connections with other lines, and thereby establish useful communication between the north-west and south-east of London. The connections of the proposed line with 17 other lines existing and proposed, having been explained, Sir Douglas Fox, on behalf of the North-West London Company, stated the objections to the proposed line crossing under the projected North-Western line near the Marble Arch. If the promoters would raise their level and join end-on with his company, his directors would be prepared to enter into an arrangement with them. The Committee adjourned to June 11.

LIGHTING AND GENERAL.

Croydon.—A main is to be laid at a cost of £1,200 to supply current to 17 houses in the Pampisford-road district.

Kyle.—Mr. Kerr, architect to the Guardians, has been asked to report upon an installation of electric lighting for the house.

Share Market.—Nothing much was doing in electric securities during the week beyond British Westinghouse preference and Metropolitans.

Submarines.—The Russian Government are building an electrically-driven submarine boat at Kronstadt, which is to be finished by the end of June.

Liverpool.—Mr. H. P. Boulnois has held the enquiry into the application of the City Council for sanction to borrow £300,000 for the purposes of electric lighting.

Canterbury.—Mr. F. H. Tulloch has held an enquiry into the Town Council's application for sanction to borrow £17,000 for the purposes of electric lighting.

Blyth.—A commencement has been made with the power station buildings of the electricity works for the Northern Counties Electricity Supply Company.

Poplar.—The loyal burgesses are clamouring for current at 3d. per unit, and are threatening that if their wish be not complied with new customers will become scarce.

Dalmeny.—The electric light is about to be installed at Lord Rosebery's residence, Barnbougle Castle, Dalmeny, by Messrs. Anderson and Munro's Edinburgh branch.

Personal.—Mr. E. T. Williams, assistant borough electrical engineer, King's Lynn, has been appointed to the position of engineer-in-charge at the Belfast Corporation electricity works.

Gloucester.—Alderman Fielding has been added to the Works Sub-Committee of the Electricity Supply Committee. Mr. Bache is obtaining estimates for the cable to be purchased for supplying the hospital.

British Thomson-Houston Co.—This firm have just issued a new list of alternate-current fan motors, which should find a ready sale while the hot weather lasts. We notice that they are designed for a frequency of 60.

Stock Exchange.—The Committee of the Stock Exchange have ordered the Aron Electricity Meter, Limited, 125,000 ordinary shares of £1 each, fully paid, Nos. 1 to 125,000, to be quoted in the official list.

Edinburgh.—At the last meeting of the sub-committee of the Electric Lighting Committee of the Town Council it was reported that the applications for the electric light during the past year were equal to 194,000 8-c.p. lamps.

Taunton.—Colonel W. R. Slacke has held an enquiry into the Town Council's application for sanction to borrow £21,000 for electric lighting purposes and £4,500 for the erection of a refuse destructor near their sewage outfall works.

Southwark.—The City of London Electric Lighting Company, Limited, intend to apply for a provisional order empowering them to supply electric energy for all purposes throughout the whole area of the metropolitan borough of Southwark.

Hoylake.—The Hoylake and West Kirby District Council have decided to light by electricity the public lamps in the streets in which electric mains are laid. We note that the supply will be available for consumers within the next few days.

Boating Accident.—The employés of Messrs. Callender's telegraph works on the 26th inst. held a club regatta off Belvedere, and we very much regret to learn that, during a heavy squall, two men, named Moir and Cobb, were drowned owing to their boat being upset.

Bridlington.—The Town Council on Wednesday adopted a resolution stating that the present is not an opportune time to carry out the Bridlington Electric Lighting Order, 1900, and that the carrying out of the order be postponed, the town clerk being instructed to apply to the Board of Trade for an extension of the period of two years.

Greenwich.—The Guardians have decided to light the schools at Halfway-street, Sidcup, by electricity, and an estimate is being prepared of the cost. The Borough Council on Wednesday passed a resolution disapproving of a provisional order being granted to the City of London Electric Lighting Company to supply electric energy for all purposes in the borough.

A Large Order.—Messrs. Ernest Scott and Mountain, Limited, of Close Works, Newcastle-on-Tyne, have, we are informed, secured the contract for the electrical equipment of the Port Talbot Steel and Iron Company's steel-rolling mills which are now in course of erection. This is probably the first new mill in which a complete installation of electrically-driven machinery has been adopted.

Penzance.—The following report was adopted at Wednesday's meeting of the Town Council: "The Electric Lighting Committee had before them a letter from Edmundson's Electricity Corporation, Limited, asking to be allowed to carry out the electric lighting order in case the Council do not see their way to carry it out, and recommend that they be asked to state the terms on which they would do so."

London Gazette.—The promoters of the City and North-East Suburban Electric Railway Company intend to petition for additional provision to authorise alteration of levels of a portion of the proposed railway and the use of land at Low Leyton for the construction of a generating station. The Ambleside Urban District Council propose to transfer their electric lighting order to the Windermere and District Electricity Supply Company, Limited.

Lancaster.—At Wednesday's meeting of the Town Council a resolution to pay £20 to Mr. Alan Fraser, late borough electrician, was defeated. It will be remembered that Mr. Fraser went out to the war as a yeoman, with the consent of the Corporation, who allowed him £1 a week during his absence. While he was away they appointed a new electrical engineer in reference to a scheme of electrical tramways. Mr. Fraser came home at his own expense, obtained a better position elsewhere, and then asked the Council to refund him part of his return fare from South Africa, which it is alleged the War Office made him pay. The Council refused on the ground that they never asked Mr. Fraser to return.

Jamesville Triplex Electric Pump.—The Jamesville Ironworks Company, of Jamesville, Pa., U.S.A., has sent us a copy of their pump circular. In it special reference is made to electric pumps for mine work, and the advantage of electric transmission is pointed out. Small pumps can be so easily erected and moved when they are electrically driven. The pumps made by the above firm are of the three-throw type. The motor is placed on the same bed-plate, with its axle extended on both sides, so that there is a double drive. A pinion, one on each end of the shaft, then gears into two large gear wheels placed one on each end of the pump axle with its three cranks. This firm standardises its pumps according to the lift required, this ranging from 350ft. up to 1,200ft.

Digitized by Google

Runcorn.—We regret to hear that on Saturday morning a fire occurred at the Wigg Chemical Works, Runcorn, belonging to the United Alkali Company, and damage was done, it is reported, to the extent of £25,000. There were several explosions, but no persons were injured.

Notting Hill.—The Notting Hill Electric Lighting Company's Bill seeking powers to provide additional station accommodation to meet "the demands for the supply of electrical energy within their area of supply," has passed the Unopposed Bill Committee of the House of Commons.

Provisional Orders.—Bills to confirm certain provisional orders made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, relating to the electric lighting of Birstall, Skipton, and Honley, have passed committee, and in due course will be reported for third reading.

Ashton-under-Lyne.—The Town Council have issued the statutory notice that they intend, in accordance with the provisions of the regulations made by the Board of Trade on Sept. 11, 1897, to apply to the Board of Trade for permission to alter the standard pressure at which energy is to be supplied.

Newark.—An enquiry is to be held into the Urban District Council's application for power to borrow £30,000 for electric light. In the meantime the Electric Lighting Committee have been instructed to consider the possibility of obtaining electricity in bulk, within a reasonable time, from the company whose Bill is now before Parliament.

Light Cure.—Mr. Alfred Harmsworth has given £10 000 to the London Hospital, Whitechapel, to endow one of the three lamps started there for the light cure of lupus. The authorities of the hospital hope that this very generous act will be followed, and that the other two lamps, one of which was presented to the hospital by Queen Alexandra, may be similarly endowed, as each lamp costs the hospital £400 a year.

Bristol.—Mr. Bird having resigned the post of station superintendent, on his appointment to the managership of the Guernsey Electric Supply Company, it has been decided to promote Mr. J. H. Bolman, B.Sc., to the vacant post. Extensions of the mains to St. Stephen's-street, Canon's Marsh, and at Redland have been sanctioned. An application for an extension in Silverthorpe-lane stands deferred.

Chichester.—The Corporation have followed with great interest the working of the electric lighting at Windsor, and have just received a report stating that the deduction to be drawn from the same was that Chichester would do well to embark on a like undertaking, taking care, however, that it was retained in the hands of the Corporation, and that the expenditure on the works was not so lavish as in the case at Windsor.

Mansfield.—The Electric Lighting Committee having decided to proceed with the electric lighting works and not to accept the offer of the Derbyshire and Notts Electric Power Syndicate to take the whole of the energy from them, preferring to erect their own generating station and lay their own mains. Specifications have been approved and the engineer has been authorised to ask for tenders, as the committee are most anxious to push on with the local scheme as quickly as possible.

Radstock.—The Urban District Council have adopted a report stating that the Lighting Committee had considered Mr. Preece's report upon an electric lighting scheme for Radstock and Midsomer Norton, and had decided to defer the matter to a future meeting of the committee, the surveyor in the meantime to make enquiries and to report further as to the relative cost of pumping at the proposed sewage works by electrical and other power, and also to report generally upon the electric lighting.

Barnet.—At the last meeting of the Urban District Council the following letter was read from the North Metropolitan Electrical Power Company, Limited: "We duly received your letter of the 8th inst. enquiring the terms upon which we should be prepared to light the new area, and having carefully considered the matter, beg to say that at present we should much prefer not to make any extensions in the directions indicated until the business has been further developed in the district we are now dealing with."

Boiler Certificates.—It has been arranged that the Parliamentary Committee to consider the Bill to grant certificates to persons in charge of steam-engines and boilers, second reading of which was agreed to earlier in the session, shall consist of the following persons and a motion to the effect is to be made at the reassembling of the House: Mr. W. W. Allan, Mr. Baldwin, Sir J. Brunner, Mr. Crean, Mr. Galloway, Sir A. Hickman, Mr. Jacoby, Mr. Nannetti, Colonel Pilkington, Sir F. Powell, Mr. Renshaw, Colonel Royds, Mr. Tomlinson, Mr. J. Wilson (Durham), and Sir T. Wrightson.

Tenbridge.—The adjourned enquiry by the Local Government Board into the Urban District Council's application to borrow £20,400 for electric lighting purposes was concluded at the Central Hall on Friday. Mr. Reader Harris, K.C., M.P., again appeared for the Council, and Mr. Atherley Jones, K.C., M.P. (instructed by Messrs. Freer, Morgan, and Brown), for the opposition on the part of the ratepayers. There was again a good attendance, incinding Councillor W. Baldwin, Councillor F. East, J.P., Councillor R. W. Annison, Councillor G. Dadson, Councillor I. Race, Mr. C. E. Warner, Mr. J. Lee, and others.

Warwick.—The Board of Trade have granted a provisional order to the British Electric Traction Company, Limited, for the supply of electricity within the borough of Warwick. The order provides that the local authority may acquire the undertaking of the company for the supply of this area within six months after the expiration of a period of 28 or 35 years from the commencement of the order on giving two years' notice. A special power is also granted to the company to enable it at any time within one year from the commencement of this order to transfer the undertaking to the Leamington and Warwick Tramways and Omnibus Company, Limited.

Weston-super-Mare.—Mr. B. Heap (chairman of the Urban District Council) and Mr. J. E. Norman (vice-chairman) last Friday switched on the current at the Weston-super-Mare and District Electric Supply Company's station. It appears that upon taking over the Council's provisional order for electric lighting, the company had undertaken to supply the compulsory area defined therein within 15 months. This period has been slightly exceeded, but the company have extended their mains considerably beyond the limits of the prescribed area. The applications number 95, with a consumption of from 4,000 to 5,000 lamps. Mr. S. G. Leech is the resident manager-engineer, and Mr W. C. C. Hawtayne the engineer representing the Council. The tramway will be supplied from the same building.

Wimbledon.—The statement of accounts of the Electric Lighting Committee just issued is considered eminently satisfactory. The accounts for the year ended March 31, 1901, show that the existing debt at that time was £65,000; the expenditure on repayment had been: principal, £1 551. and interest, £1 483; and working expenses were £6,338—total expenditure, £9,373. The revenue from private consumers was £5 479; from public lighting, £4 028 a total of £9 508; leaving a balance of profit for the first time of £134. 9s. 7d. The engineer has been authorised to carry out cable extensions in the following roads at an estimated cost of £105: Woodside, Spencer-hill, Queen's-road. The estimate of capital expenditure for the 12 months ending March 31, 1902, is £7 500 and application is to be made for sanction to the borrowing of this amount.

French Manners.—From the Paris chief telephone exchange comes the following story, which, if true, is typical of the excitable and self important personages whose rudeness towards ladies may be observed daily at any Paris tramway or railway terminus: A well-dressed man called and asked which office he was connected with He was shown into the room of the lady superintendent, and immediately made a violent assault upon her, boxing her ears with closed fists, while he exclaimed, "So you are one who makes a fool of me whenever I ring you up." The lady screamed loudly for help, and the police had to be called in to remove him to the lock-up, where he stated that he had been so incensed at the muddle the telephone clerks made of his calls that he determined to teach some of them the lesson that he was not to be played with.

Blackburn.—Mr. A. S. Giles, the borough electrical engineer, has just issued his annual report on the working of the electricity department during the past year. The receipts are stated at £14 465. 3s. 5d., against £11,843. 10s. in the previous year, an increase of 22 per cent., while the expenses have been £9,383. 1s. 10s., against £7,135. 0s. 2d., leaving a gross profit of £5,082. 1s. 7d., against £4,078. After paying the interest and sinking fund charges there is a balance in hand of £273. 7s. 8d., against £19. 1s. last year. The cost of generating in the works has been reduced from 1·65d. per unit last year to 1·32d., and the total costs, including management and distribution to the consumers, from 2·07d. per unit to 1 78d. There is an equivalent of 56 524 lamps of 8 c.p. connected to the mains, an increase of 10 524 over the previous 12 months. During the year applications were received for supply to 54 additional motors, which now total 94, or an aggregate of 280 b.h.p. The number of consumers taking the supply for all purposes is 670, an increase of 66 over last year, and the average price obtained per unit sold is 2·7d. The total output from the works for the year is 1,159,861 Board of Trade units sold, an increase of about 53 per cent. over last year's production, and during the year two additional generators have been put down of 256 kw. each, which brings up the capacity of the works to 3 280 h.p. The maximum load on the works at any one time was 1.112 kw. on March 23 last. Mr. Giles advises a uniform charge of 2s. per quarter for all meters up to 50 amperes. He says the number of meters in service is 692, costing about £3,114. The market price to-day for a meter up to 50 amperes is £4. 10s. The present rentals are 2s. 6d. per quarter each up to 25 amperes, and 5s. per quarter for one of 50 amperes capacity.

Islington.—At last Friday's meeting of the Borough Council a report was received from the Electric Lighting Committee stating that they had had under consideration the difficulties which confront them in connecting consumers in streets where supply mains are laid owing to the restriction contained in Standing Order No. 12, that "no contract shall be entered into or liability incurred for works proposed to be paid for out of capital until the consent of the sanctioning authority to the borrowing has been obtained." They recommended that Standing Order No. 12 be altered by the addition of the following words: "Except in the case of low-tension distributors and services required to connect consumers of electricity with the Council's mains which may be laid, after being sanctioned by the Council, as and when authorised by the Lighting Committee." This was passed subject to the condition that the Lighting Committee submit quarterly to the Finance Committee a statement of the amount so expended, with plans showing where the work has been carried out. The Council also agreed to a report of the Lighting Committee stating that the late Vestry authorised extensions of mains in Hornsey-road, and that the cost of such mains was included in a loan, sanction to which has been granted

Digitized by Google

by the London County Council. As some technical questions connected with the system of laying the mains were under consideration by the Board of Trade, and time must necessarily elapse before any definite conclusion is arrived at, the committee thought this work should be proceeded with, and with that view they had obtained an estimate from the electrical engineer of the cost, calculated on the same basis as was used in preparing the estimates for the original loan, which amounts to £10,530.

London County Council.—In connection with the Holborn-to-Strand improvement the Council is acquiring from the Metropolitan Electric Supply Company, Limited, their station buildings, machinery, and works in Sardinia-street. Section 55 of the London County Council (Improvements) Act, 1899, requires the Council to convey to the company a new site, to pay "a sum equal to the costs and expense of erecting and fitting up a new generating station upon the new site with new plant of a capacity to generate and supply electrical energy to an output of not less than 4,000 kw.," and to fulfil other conditions. The company contended that the sum to be paid to them ought to include the value of spare or stand-by plant, and that the normal capacity of the entire plant ought to be not less than 5,000 kw.; but the Improvements Committee were advised that there was no obligation upon the Council to pay the cost of erecting and fitting up a new station with plant of a capacity to generate a supply, under ordinary circumstances, of more than 4 000 kw. Accordingly an action against the company was commenced by the Council in the Chancery Division for a declaration as to the rights of the parties under the Act; and Mr. Justice Farwell decided in favour of the Council's contention. The company appealed against this decision. Lords Justices Collins and Stirling, who heard the appeal, disagreed with the judgment of Mr. Justice Farwell, and decided that it was open for the arbitrator to say whether or not any spare or stand-by plant was necessary. The appeal was accordingly allowed. Notice of appeal is now to be given against the decision of the Court of Appeal in the action by the Council against the Metropolitan Electric Supply Company, Limited. Notices under Electric Lighting Acts and Orders have been approved of as follows: the Central Electric Supply Company, under the company's Act of 1899, to lay extra high-tension mains from the company's generating station along Lodge-place, Grove-road, Rossmore-road, Harewood-avenue, Marylebone-road, Gloucester-place, Portman-square, Lower Seymour-street, James-street, Oxford-street, and along Wigmore-street, Cavendish-square, Margaret-street, Regent-street, and Great Portland-street; the County of London and Brush Provincial Electric Lighting Company, under the County of London (Northern Extensions) Order, 1897, to construct a transformer box in Cross-street, Hatton-garden; the London Electric Supply Corporation, under its order of 1889, to construct an underground converter box in Manning-street, Bermondsey, and under the same order to lay trunk and high-tension distributing mains across Waterloo-road and along Exton-street; the Metropolitan Electric Supply Company, under the West London Order, 1889, to lay low-tension mains along portions of Mortimer-street and Great Portland-street, and also to lay high-tension mains along and across Marlborough-hill, and along Circus-road and Lennard-place, and under the Paddington Order, 1890, to lay high-tension mains along and across Shirland-road; the St. James and Pall Mall Electric Light Company, under the St. James Order, 1890, to lay extra high-tension mains along Oxford-street, Argyll street and place, Carnaby-street, Ganton-street, and Marshall-street to the company's station; the Westminster Electric Supply Corporation, under the Westminster Order, 1889, to lay extra high-tension mains along Robert-street, Gilbert-street, Providence-court, North Audley-street, Green-street, Park-lane, Hamilton-place, Hyde Park-corner, Grosvenor place and gardens, Ebury-street, Belgrave-road, Eccleston-place, Charlwood-street, Vincent-square (two sides), Carey-street, Regent-place, Horseferry-road, and Millbank-street, and to construct four underground chambers; the St. Pancras Borough Council, under the St. Pancras (Middlesex) Order, 1883, to lay mains along Park-street, Albert road and terrace, and Savernake-road, and along Charlotte-street and Stephen-street.

LIGHT RAILWAYS.

An enquiry has been held into the proposed Wales and Laughton light railway order.

We understand that the provisional order granted by the Light Railway Commissioners for extensions of the Barnsley and district light railway has been confirmed by the Board of Trade.

The promoters of the proposed light railway to the Lizard propose to work the railway by electricity instead of steam, an offer having been made to provide the greater part of the money required to construct the line on condition that it was worked electrically, and that level crossings were substituted for bridges.

The Middlesex County Council are about to apply for four orders, involving the construction of about 75 miles of light railways, at an estimated cost of £25,000 per mile. Application is also to be made (1) for the construction of a light railway from Holmfirth to Southowram, near Halifax, for goods traffic only, of which Mr. Myers Beswicg, of Leeds and Westminster, is the engineer for the scheme, and Messrs. Land and Foster, Halifax, the solicitors; (2) for the construction of two lines in the parishes of Melton Bromeswell, Sutton, Shottisham, Hollesley, Alderton, and Bawdsey, to be called the Woodbridge District and Bawdsey Light Railway; and (3) of a line in Woolwich, Greenwich, Eltham, Charlton, and Kidbrook.

The fourth annual statement just issued by the Commissioners shows that since the date of the last report the Treasury have conditionally agreed to make the following advances in respect of light railways authorised by orders confirmed by the Board of Trade: Leek, Caldon Low, and Hartington (Waterhouses to Hulme End section), £5,000, in addition to £10,000 previously promised; Tanat Valley, £10,000, in addition to £18,000 previously promised; Welshpool and Llanfair, £7,500, in addition to £7,000 previously promised; Wick and Lybster, £5,000 as a free grant and £3,000 as a loan without interest, in addition to £20,000 previously promised. The Treasury have also conditionally agreed to advance sums in respect of certain orders approved by the Light Railway Commissioners, but not yet submitted to the Board of Trade for confirmation—viz., Cromarty and Dingwall, £25,000 as a free grant and £12,500 as a loan without interest; Elsenham, Thaxted, and Bardfield, £3,250, in addition to £16,000 previously promised.

Fifty-six applications for orders to authorise light railways were made in the year 1896-7; 65 in the year 1897-8; 94 in the year 1898-9; 67 in the year 1899-1900; and 27 in the month of November, 19,000. The Commissioners' report deals with 126 orders (in respect of 133 applications) which they have submitted to the Board of Trade for confirmation. On Dec. 31, 1899, 18 orders were before the Board of Trade for consideration. Of these, 13 were confirmed by the Board during the year under report, and five were held over for various reasons, one of them having since been confirmed. In the course of the year the Light Railway Commissioners submitted 40 fresh orders to the Board for confirmation. Objections to the confirmation of the orders were lodged with the Board of Trade in most instances, and in each case a day was appointed for the consideration of the order, and an opportunity of being heard was given to objectors. The Board of Trade also considered each order with special reference to the points mentioned in Section 9 of the Light Railways Act, and made various amendments in the orders. Sixteen of such orders, in addition to 13 previously mentioned, were confirmed by the Board of Trade during the year. The remaining orders—24 in number—were still under consideration on Dec. 31 last, but of these 10 have since been confirmed.

The orders dealt with by the Board of Trade during the year 1900 are recapitulated as follows; (*a*) Orders under consideration on Dec. 31, 1899—*Kelvedon, Tiptree, and Tollesbury (held over at request of promoters); Derby and Ashbourne (under consideration); Abergavenny and Monmouth (held over at request of promoters); Redditch and District, Callington, Basingstoke and Alton (Amendment), Dudley and District (Extensions) and Gosforth and Ponteland; South Staffordshire (confirmed), Cheltenham and District (confirmed), North Lindsey (confirmed), North Lincolnshire (confirmed), Isle of Thanet (Extensions) (confirmed), Essington and Ashmore (confirmed), Rhyl and Prestatyn (confirmed), and Mid-Suffolk (confirmed); Aldershot and Farnborough (consideration deferred pending the completion of negotiations between the promoters and the War Office); Waltham Cross and Enfield (consideration deferred pending the submission of the Middlesex light railways order now before the Light Railway Commissioners). (*b*) Orders submitted for confirmation during the 12 months ended Dec. 31, 1900: East Anglian (consideration deferred pending result of proceedings on Lowestoft Corporation Bill in Parliament); Cheltenham and District (Extension), Bishop's Waltham, Bexhill and St. Leonards, Highbridge, Wedmore, and Cheddar, Robertsbridge and Pevensey, South Staffordshire (Extensions), Bere Alston and Calstock, Lastingham and Rosedale, North Wales Narrow-Gauge Railways (Beddgelert Light Railways Extension), Bourne Valley, Barnsley and District, Gateshead and District, Peterborough and District, Bromsgrove, Rhyl and Prestatyn (Extensions), and Wotton-under-Edge (confirmed); *Ormskirk and Southport, *Long Melford and Hadleigh, *Maidstone and Faversham Junction, Spen Valley (Extensions), *Brackenhill, *West Hartlepool (Deviation, etc.), and Spen Valley (under consideration); Colne and Trawden, Barrowford, Nelson, and Leighton Buzzard and Hitchin (waiting action on the part of promoters); Nuneaton and District and *Oakington and Cottenham (waiting action on the part of promoters): Aldershot and Farnborough (Extension) (consideration deferred, pending the completion of negotiations between promoters and the War Office); *Sheerness and District and *Morley and District (with counsel for settlement); Dartford District (action deferred, pending result of negotiations between promoters and certain objectors); East and West Yorkshire Union, Tickhill, *Nidd Valley, Bridgwater, Stowey, and Stogursey, Loughborough and District, and *Cleobury Mortimer and Ditton Priors (time for lodging objections not yet expired. * Since confirmed.

The orders confirmed since the passing of the Light Railways Act, are as follows: 1897 (1 to 4) Basingstoke and Alton, East

Digitized by Google

and West Yorkshire Union, Potteries, Hadlow. 1898 (5 to 30)—Wrington Vale, Flamborough and Bridlington, Crowland and District, Lizard, Lauder, Forsinard Melvich and Port Skerra, Gifford and Garvald, West Highland Railway (Loch Fyne), Bridlington and North Frodingham, Caledonian Railway (Leadhills and Wanlockhead), Carmyllie, Great Western Railway (Pewsey and Salisbury), West Hartlepool, Isle of Thanet, Dornoch, North Sunderland, Vale of Rheidol (Aberayron Extension), Goole and Marshland, Pewsey and Salisbury (Devizes Branch), Amesbury and Military Camp (L. and S.W. Railway), North Holderness, Gower, Dudley and District, Bankfoot, St. George and Hanham, Middleton. 1899 (31 to 65)—Tanat Valley, Flamborough and Bridlington (Amendment), Barking and Beckton, South Norfolk, Didcot and Watlington, Grimsby and Saltfleetby, Leek, Caldon Low and Hartington, North Shields, Tynemouth and District, Kinver, Ventnor Inclined, Liverpool and Prescot, Isle of Axholme, Sheppey, London United, Merthyr Tydfil, West Manchester, Llandudno and Colwyn Bay, Axminster and Lyme Regis, Corringham, Chatham and District, Poole and District, Penzance, Newlyn and West Cornwall, Trent Valley, Portsdown and Horndean, Fraserburgh and St. Combs, Welshpool and Llanfair, Southend-on-Sea and District, Glasgow and South-Western Railway (Maidens and Dunure), Didcot and Watlington (Extensions), Coggeshall, Bradford and Leeds, Doncaster Corporation, Wick and Lybster, Cranbrook and Tenterden, Glasgow and South-Western Railway (Cairn Valley). 1900 (66-94)—Basingstoke and Alton (Amendment), North Lincolnshire, North Lindsey, Essington and Ashmore, Redditch and District, Isle of Thanet (Extensions), Dudley and District (Extensions), Rhyl and Prestatyn, Mid-Suffolk, Callington, Bexhill and St. Leonards, Cheltenham and District, Cheltenham and District (Extensions), Robertsbridge and Pevensey, Highbridge, Wedmore, and Cheddar, Bere Alston and Calstock, Lastingham and Rosedale, North Wales Narrow-Gauge Railways (Beddgelert Light Railway Extension), Barnsley and District, South Staffordshire, Gateshead and District, South Staffordshire (Extensions), Bromsgrove, Peterborough and District, Bourne Valley, Bishop's Waltham, Gosforth and Ponteland, Wotton-under-Edge, Rhyl and Prestatyn (Extensions). 1901 (95 to 105)—Oakington and Cottenham, Long Melford and Hadleigh, Sheerness and District, West Hartlepool (Deviation, etc.), Ormskirk and Southport, Kelvedon, Tiptree, and Tollesbury, Morley and District, Maidstone and Faversham Junction, Brackenhill, Cleobury Mortimer and Ditton Priors, Nidd Valley.

NEW COMPANIES.

The following new companies have been registered since our last issue:

Birkdale District Electric Supply Company, Limited.—Capital, £30,000. Object: to carry on in the United Kingdom and elsewhere the business of electrical engineers and contractors, suppliers of electricity, carriers of passengers and goods, electricians, etc.

Straker Steam Vehicle Company, Limited.—Capital, £12 000. Object: to acquire from S. S. Straker the benefit of certain existing inventions belonging to him in connection with steam-motor vehicles, and to carry on the business of mechanical and electrical engineers, etc.

Lewis Lighting System, Limited.—Capital, £15,000. Object: to adopt an agreement with E. Dalton; to acquire and turn to account any patents, inventions, licenses, concessions, and the like relating to improvements in the production of acetylene gas, and to carry on the business of electricians, engineers, lampmakers, etc.

Fuller, Macleod, and Co., Limited.—Capital, £10,000. Object: to acquire the business carried on at 9, Red Lion-court, E.C., by J. L. Fuller, as Fuller and Co., and to carry on the business of merchants, factors, dealers in electrical accessories and equipment, dynamos, motors, electrical engineers, makers of electrical and general engineering appliances, etc.

Eagle Engineering and Motor Company, Limited.—Capital, £6,000. Object: to adopt an agreement with R. Jackson of the one part and J. Kenworthy and J. B. Bindloss, jun., for the company of the other part, and to carry on the business of engineers, electricians, wheelwrights, tube makers, screw, bolt, and nut manufacturers, motorcar makers, etc.

Millington, Everitt, and Co., Limited.—Capital, £3,000. Object: to acquire from F. Millington the benefit of certain existing inventions, and to carry on the business of electricians, suppliers of electricity, manufacturers of and dealers in electrical, galvanic and magnetic apparatus, electrical and general engineers, cycle and motorcar manufacturers, etc.

Dolter Electric Traction Company, Limited.—Capital, £100,000. Object: to acquire inventions, licenses, concessions, etc., relating to the production, treatment, storage, application, distribution, and use of electricity, in particular to acquire from the Société d'Exploration des Brevets Dolter, of 12, Rue la Fayette, Paris, the benefit of certain patents and patent rights in respect of certain inventions relating to electric traction, or apparatus therefor, and to carry on the business of an electric traction and supply company, etc.

PROVISIONAL PATENTS, 1901.

MAY 13.

9911. Improvements in or in connection with direct-acting engines applicable for coal cutting, mining, drilling, tunnelling, stamping ore, pile driving, and the like. Sir Thomas Wrightson, Bart., M.P., and John Morison, 24, Southampton-buildings, Chancery-lane, London.

MAY 18.

10349. Method of and apparatus for mitigating the danger, with the object of preventing the loss of life, that is attendant upon the rush of steam from a burst or broken steam-pipe, particularly such as the high-tension engines of battleships, cruisers, liners, etc., are liable to. Charles Mackintosh, 159, Euston-road, London.

MAY 20.

10377. Main controlling electric switch. Sarah Dixon and Son, Limited, Boar-lane, Leeds.

10434. A process of increasing and decreasing the internal resistance of vacuum tubes. Alfred Ernest Dean, 73, Hatton-garden, London.

10459. Improvements in storage batteries. Vincent Groby Apple, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 21.

10480. Improvements relating to telephonic systems. Arthur Henry Hickley, 10 St. George's-crescent, Liverpool.

10482. A cell for electrolysis. Arthur Alexander Govan, 15, Renfield-street, Glasgow.

10505. Improvements in storage batteries. Thomas Alva Edison, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10506. Improvements in magnetic separating apparatus. The Edison Ore-Milling Syndicate Limited, 188, Fleet-street, London. (Thomas Alva Edison, United States.) (Complete specification.)

10599. A new or improved telephone receiver holder. George S. Meyer, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Dec. 8, 1900, being date of application in United States.)

MAY 22.

10562. Improvements in dynamos and electric motors. Stainer Hutchins, 57, Barton-arcade, Manchester.

10569. Improvements in means or apparatus for preventing contact of telephone and telegraph wires with the trolley wires of electric tramway installations. Walter William McLauchlan, 62, Market-street, Manchester.

10571. Improvements in junction boxes for electric wire and like installations. George Hubert Woods, 55, Market-street, Manchester.

10587. Improvements in electrical lampholders. George Sperryn and William Henry Wood, 104, Colmore-row, Birmingham.

10609. Electromagnetic electric railway-track switch and means for controlling and operating same. Philip Benjamin Williams, 31, Cannon-street, London.

10623. An improvement in telephone apparatus. Arthur Harold Nicholson and the New Phonopore Telephone Company, Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on June 15.

1900.

3343. Telegraphic transmitting, receiving, and translating arrangements. Muirhead.

3535. Electricity meters and electric clocks. Hookham.

9339. Multiplex telephony. Evans. (Faller.)

9631. Detective lock or seal for gas and electric meters, electrical demand indicators, and fuse boxes, or for any other uses or purposes to which same may be applicable. Bastian.

9744. Electric signalling apparatus. Lea and Taylor.

11054. Electrically-operated cloth-cutting machines. Garland.

11207. Distribution of electricity. Andrews.

11287. Conduits for electric conductors. Jones.

11941. Regulating appliances in connection with electric motors for turret turning, gun training, and analogous purposes. Scott.

19425. Electric coherers. Ducretet.

23240. Gear cases for electric cars. Cox, Smith, and Smith.

1901.

5077. Devices for X-rays. De Mare.

5220. Electric surgical dilators. Mosher. (Date applied for under International Convention, Aug. 25, 1900.)

5700. Electric clocks. Pöschl and Gaütsch.

8102. Switch systems for telephone circuits. Cerebotani and Moradelli.

Digitized by Google

7492. Winding for electromagnetic inductive apparatus. Wait. (Date applied for under International Convention, Jan. 12, 1901.)

8162. Electrical lamps. Feeny. (Allgemeine Elektricitäts-Gesellschaft.)

8196. Sockets or holders for incandescent electric lamps. Uytenbogaart.

NOTES.

Incorporated Gas Institute.—The thirty-eighth annual general meeting of this institute is fixed to be held at the Royal United Service Institution, Whitehall, London, on the 11th, 12th, and 13th inst., under the presidency of Mr. T. Ormiston Paterson, M.I.C.E. On the first day the proceedings will open at 10.30 a.m., and on the two subsequent days at 10 a.m. respectively.

Oil-Fields in Texas.—The recent development of the oil-fields in Jefferson County, Texas, has, according to an American contemporary, resulted in marked prosperity for other interests. The Houston Electric Street Railway, for instance, is now burning oil from the fields near the town of Beaumont, and, it is said, will thus save £1,300 per annum in their fuel bill. The price obtained for this Beaumont oil is just over 2s. per barrel.

American Municipal Electricians. — We are informed that the sixth annual convention of the International Association of Municipal Electricians of New York will be held this year in the Natural Food Company's Conventional Hall, Niagara Falls, on Sept. 2, 3, and 4. From present appearances this promises to be one of the best meetings ever held by the association, both as regards attendance and subjects to be brought before the convention. Full particulars may be had on application to Mr. F. C. Mason, 16, Smith-street, Brooklyn, N.Y.

Personal.—We note that it is in recognition of his numerous scientific works, as well as of his inventions, that Dr. Karl Auer von Welsbach has been made a baron by the Emperor of Austria. In this country Dr. Welsbach is best known in connection with the incandescent light which bears his name, but it is said that he is now seeking to do for electricity what he has already accomplished in respect of gas. The baron, who is still a young man, being only 42 years of age, comes of an inventive stock, and his father, who founded the State printing office in Vienna, was also an inventor in typography and xylopyrography.

German Visit to the States.—According to a note in *Electricity*, a party of engineers and other experts connected with German street railways will arrive in New York this week for the purpose of studying the different systems of electric tramways in vogue in America. It is stated that the German engineers will not be empowered to close any contracts for material, equipment, etc., with American manufacturers, their sole object being to gather data for submission to their respective executive officers. The result anticipated from this course is that substantial orders will be placed with United States firms. It is of interest to note that this is the first visit of German electrical experts to America.

The "Henry Angel Memorial."—A movement is on foot among the former students and colleagues of the late scientist, Prof. Henry Angel, to perpetuate his memory by founding a prize or scholarship to his name at the City of London College. For many years Prof. Angel taught steam, applied mechanics, and practical plane and solid geometry with signal success both at this college and elsewhere, and in spite of natural infirmities he laboured so unceasingly as to gain the highest esteem of all his pupils. It is felt that there are many members of the profession who would be glad to associate themselves with the movement, and subscriptions may be sent to Mr. P. J. Gillbard, hon. secretary of the fund, City of London College, White-street, E.C.

Determination of the Boiling Point of Liquid Hydrogen.—An abstract of a paper by Mr. James Dewar describing a method of determining the boiling point of liquid hydrogen by hydrogen and helium gas thermometers appears in the June number of the *Journal* of the Chemical Society. In this case the author states that a constant-volume thermometer, charged with hydrogen or helium, has been used. It is shown by a number of experiments that either a simple or a compound gas at an initial pressure somewhat less than one atmosphere may be relied on to determine temperatures down to its own boiling point in the constant-volume gas thermometer. The mean values of separate determinations give −182·5deg. as the boiling point of oxygen, and −252·5deg. as that of hydrogen. The latter is lower than the value −238·4deg. previously obtained with a platinum-resistance thermometer.

Institution "Journal."—The April issue of the *Journal* of the Institution of Electrical Engineers contains the following papers with the discussions thereon: "The Use of Aluminium as an Electrical Conductor, with New Observations upon the Durability of Aluminium and other Metals under Atmospheric Exposure," by Mr. J. B. C. Kershaw; "Capacity in Alternate-Current Working," by Mr. W. M. Mordey; "The Electrical Power Bills, 1900; Before and After," by Mr. W. L. Madgen; "The Dublin Corporation Electric Light Scheme," by Mr. R. Hammond (Dublin Section); "Electrically-Driven Machine Tools and their Advantages for Use in Engineering Workshops," by Mr. G. Ralph (Newcastle Section); and "A Method of Compensating Voltmeters for Voltage Drop in Long Feeders," by Mr. M. B. Field (Glasgow Section). The volume concludes with an original communication from Mr. A. Russell, entitled "Note on Resonance with Alternating Currents."

Cold Splicing of Electric Cables.—A new device for splicing electrical conductors without the outside application of heat has recently made its appearance on the American market. The new method, which has been introduced by the Morris Electric Company, is to remove the insulation for a short distance from the ends of the cable or wire, and then insert the ends in a short sleeve of copper of high conductivity. In describing this invention the *Street Railway Review* says the joint is then compressed into a solid mass, the external crevices of the cable being filled with a metal of the sleeve, making an air-proof and moisture-proof splice. The surface of contact between the cable and the sleeve is about nine times the sectional area of the cable, thus ensuring a joint of low resistance. The whole operation is done cold, and completed in a few seconds, and, it is reported, the joint is even stronger than the cable itself. These machines, we understand, are coming to be extensively used both in the States and abroad.

Wireless Telegraphy in the United States Navy.—The question of the introduction of wireless telegraphy into the United States navy has recently been occupying the attention of a specially appointed Board, who have investigated the matter, and made, among others, the following recommendations: that the use of homing pigeons be discontinued as soon as wireless telegraphy is introduced into the navy; that pending such action, no new pigeon cotes be established; and that wireless telegraphy be adopted by the navy for the transmission of messages between distant points. In the opinion of the Board, the successful operation of any system of wireless telegraphy demands a high degree of special electrical training, and they therefore suggest the establishment of two stations sufficiently far removed from each other for the training of both officers and men. This requirement, it is thought, would be best met by having stations at the Naval Academy, Annapolis, and the Navy Yard, Washington.

Apparatus for Decomposition Voltages.—In a recent paper under this title Mr. Wilder D. Bancroft

Digitized by Google

describes a modified form of Le Blanc's method, by means of which the conditions under which metals can be separated, the existence of a complex ion, the conditions for a crystalline deposit, etc., can be easily investigated. From an abstract of the paper in the *Journal* of the Chemical Society we gather that in this arrangement a mil-ammeter is interposed in the main circuit containing the electrolytic cell, and the electrodes are connected with a high-resistance voltmeter having a contact key in this circuit. The voltmeter should be placed in series with another high resistance, and under these circumstances the resistance of the solution can be neglected. The electrodes are platinum wires, and the cell may be in the form of a beaker or a U-tube. The measurements made are potential differences, and not E.M.F.'s of polarisation. The value of the decomposition voltage can be arrived at by extrapolation to the point of zero current. The measurements are probably correct to about 1/50 volt. The results obtained with solutions of zinc sulphate and sulphuric acid agree well with those found by Le Blanc.

Proposed Electrical Museum.—The Council of the Institution of Electrical Engineers have at present under consideration the formation of a museum for objects or apparatus not now in commercial use, but possessing interest in connection with electrical science and its application. Probably many members have in their possession apparatus or specimens of the types required, and it is felt that there is considerable danger that in the course of time they may become dispersed and entirely lost sight, unless steps be taken to guard against such a contingency. To prevent the irretrievable loss to the profession of the many objects of historical interest that are still in existence, the Council invite members and their friends to-operate either in the collection or in the tabulation of such apparatus as may be available. The authorities at the South Kensington Museum have promised to receive such of the objects as may appear to them to be of sufficient public interest as a loan collection from the Institution until the Institution is in a position to exhibit them in a home of its own. It is particularly requested, however, that objects offered to the Institution should not be forwarded until intimation is sent that the Council is in a position to receive them.

Glasgow Tramway Accidents.—We notice that the starting of the electric trams on the main streets of Glasgow has been followed, as it always has been in other cases, by an increase in the number of accidents to passengers on the cars and to the general public in the streets. It is a curious thing that the greater speed should upset, as it does, the experience of years with respect to crossing streets. For instance, in Glasgow they have had electric cars running on one route for the last two years, and the people who use that route have become quite accustomed to the speed of the cars. As soon, however, as a new route is opened, a new set of inhabitants has to get used to the fact that the cars are running faster than when pulled by horses, and it is again shown that a certain number of accidents are required to enforce ordinary care. We notice, too, that a large number of the accidents in Glasgow were brought about by the passengers getting off the cars at full speed without making due allowance for the same. Up to the present, however, we are pleased to note that the Glasgow papers have not written the "scare-headed" articles on the subject which we have often seen in the local papers of other towns when electric tramways have been opened. The decrease in the number of accidents per week will, of course, take place as the people become more careful in crossing the streets and getting off the cars.

Electric Omnibuses.—Our readers will remember that at the meeting of the British Association at Bradford last year Mr. J. G. W. Aldridge described an electric omnibus which had been devised in Paris, and which took its power from two trolley wires suspended on one side of the street along which the omnibuses ran. In this case there was a most ingenious arrangement by which the collectors on the trolley wires were made to automatically run at the same speed as the 'bus. The connecting cord then between the 'bus and the collectors was not required to transmit any mechanical stresses, and could be paid out and wound in to permit of the omnibus running at a considerable distance from the line. We note in the current issue of the *Electrical Review* of New York that a Mr. A. B. Upham, of Tremont-building, Boston, has been working at the same problem, but up to the present his solution seems to us to be much more crude than that described by Mr. Aldridge. In Mr. Upham's scheme horizontal trolleys are used to bear against the trolley wires. While the supports of these two trolley poles could be fixed at a considerable height above the omnibus, there would not even then be the clear headway between the omnibus and the trolley wires which is required to enable vehicles to pass on the inside of the electric 'bus. Again, we think the inventor would find there was considerable trouble in working the horizontal trolley.

The Bowman Lindsay Monument.—The committee entrusted with the selection of the monument which is to be erected to mark the grave of James Bowman Lindsay, whose fame as a pioneer in electrical science is generally acknowledged among electricians, have decided upon the design to be adopted. The monument consists of a lofty column of grey granite, mounted on a graded base, with simple classical ornamentation. The total height will be 19ft. 3in., and the width 4ft. Surmounting the pillar is a bronze hand holding a thunderbolt, typifying man controlling electric energy. The front of the monument bears an inscription testifying to Lindsay's services as "a pioneer in electrical science." The inscription also embodies the following passage: "He devised an electric telegraph in 1832, suggested welding by electricity, produced a continuous electric light in 1835, proposed a submarine Transatlantic telegraph in 1843, and accomplished wireless telegraphy through water in 1853." In accordance with a suggestion thrown out by Sir John Long some time ago, passages from Bowman Lindsay's own writings are engraved on both the south and north side of the monument. It is thought that the appearance of the monument will be much improved by the placing of a granite kerb around the grave, and subscriptions for that purpose and for the completion of the work will be received by Mr. A. H. Millar, *Dundee Advertiser* Office, Dundee.

Mr. Edison and the General Electric Company.—The retirement of Mr. Thomas Edison from the directorate of the General Electric Company is regarded in the States from different points of view. The New York *Journal*, for example, refers to Mr. Edison as being "thrust from the directorate," and expresses the opinion that it is the wish of the capitalists behind the company and its officers to "dissociate from it not only Edison's name, but his personality." Mr. Edison's case is that he sent in his resignation two years ago, but it was not accepted or acted upon. A few weeks ago there was a pressing call for his attendance at a meeting of the company, and he responded at great personal inconvenience to himself. It was on this occasion that he urged that his resignation from the Board be accepted. The result was the dropping of his name, and it is said in some quarters that Mr. Edison's relations with the General Electric Company are

Digitized by Google

now, as they ever have been, entirely cordial. His retirement from the directorate is put down solely to the fact that he cannot afford the time necessary to attend to the duties of the position. In the American technical Press the fact that Mr. H. P. Fish, who has been elected a director in the place of Mr. Edison, is the newly-elected president of the American Bell Telephone Company and the American Telephone and Telegraph Company, is regarded as a sign of closer friendship between the three companies.

Telephonic Communication on Tramways.—We have not heard of any device in use in this country by which those in a tramway office can open up a telephonic communication with the conductor of a car out on the road. The *Street Railway Review*, however, gives a description of a system, devised by the engineers for the Massachusetts electric companies, which is said to accomplish this purpose. The essential feature of the invention would appear to be a series of semaphores, one of which is placed near every telephone instrument along the line. From a diagram given in our contemporary, we gather that when a dispatcher in the office desires to speak with a conductor on any particular car, he closes a switch which causes to be exposed at each instrument on the line a red semaphore with the word "phone" painted on it. As the conductors of the several cars on the road reach these signals they immediately call the dispatcher on the telephone, and the signals are left in the "calling" position until the particular conductor required has responded. The dispatcher then switches the signals back, and they return to "clear" at once. Of course, it might very possibly happen with this system that two or three conductors that were not wanted would answer the call, but the dispatcher, by keeping careful track of his cars, can set the signals when he knows the desired car is nearing an instrument. No batteries are used in this device, as the signals are operated by current taken from the tramway circuit.

Illumination of Different Kinds of Glass.—In the *Journal* of the Chemical Society for June will be found an abstract of an interesting paper on this subject by Mr. Walthère Spring. Ruby glass, the author states, is made by the addition of traces of gold chloride to an ordinary fused glass. The glass so obtained is at first colourless, and only assumes a ruby colour during subsequent prolonged heating. When an intensely luminous electric beam is passed tangentially through a small cylinder of the colourless gold glass, practically no internal illumination is visible. In the case of the ruby glass, however, a yellowish-brown luminous trace is produced, probably due to reflection from minute particles of metallic gold. The intensity of colour of the ruby glass depends on the time of its reheating, and determines the intensity of illumination necessary to produce a visible trace. The deeper the colour of the glass, the less illumination is required. In the colourless glass the gold probably exists in a state of extreme sub-division, and the reheating which produces the ruby colour brings about a coarser colloidal aggregation similar to that which takes place in gelatino-bromide plates during maturation. Red glass coloured by copper and yellow glass coloured by silver show respectively dull brown and greyish luminous traces, due to the finely-divided metals. Glasses coloured by silicates of iron, chromium, manganese, and cobalt show only a faint luminous trace, and, allowing for the presence of small air-bubbles, are optically "void." Glasses which are colourless of themselves show a faint bluish trace, and are yellow when viewed through a great length. They thus resemble media containing an extremely minute turbidity. Glass decolorised by manganese compounds shows an intensely green fluorescence, the luminous trace being green when the incident light is either violet or blue, but suppressed when it is green, yellow, or red. Glasses containing iron alone or manganese alone are not fluorescent.

Electric Lighthouse.—The first installation of the electric light for lighthouse purposes in Australia was made so far back as 1883, yet even now it is looked upon as one of the grandest examples of electric lighting of which the Southern Hemisphere can boast. The Macquarie lighthouse, at the entrance to Port Jackson, indeed, is itself one of the finest in the world, and by its presence the entrance to Sydney Harbour is made perfectly safe, except during the most violent weather. We gather from a note in the *Journal* of the Society of Arts that the light is of the first order, sixteen-sided, dioptric, holophotal, revolving white light of the system of Fresnel. A flash of eight seconds every minute is obtained, and although it is stated to have a range of 25 miles seward, this is by no means the limit of distance at which the flash can be distinctly discerned. The whole apparatus is carried on a round pedestal, which offers the great advantage of enabling the keeper to enter without interfering with the rotation of the arrangement. A duplicate set of apparatus for using the electric light is also set up in this lighthouse, and, as an additional precaution, arrangements are made to burn either gas or paraffin oil. Again, the electric light may be exhibited at full power or half power at will. Although the Australian coast is remarkably free from dangers to navigation, lighthouses have been erected at every available point on the coast. The whole of the New South Wales coast is efficiently lighted, but it is expected that under the rule of the Federal Government still further improvements in this direction will be effected.

Engineers and Contractors.—It frequently happens that the interests of a consulting engineer and the interests of the contractors who work under him are not the same, although, of course, in the long run they both work with the same object—*i.e.*, to give the utmost satisfaction at the least cost. The question then arises as to how far the consulting engineer who has to advise a corporation, and to superintend the carrying out of large works, is right when he ignores the tender of a contractor whose work he is not acquainted with, or who has not, in his opinion, the experience to enable him to carry out the work. In this last case our sympathies lie with the consulting engineer, and we think that he should be sufficiently straightforward and have sufficient influence with his corporation to refuse the lowest tender if in his honest opinion the firm who have sent it in have not the requisite experience. Otherwise, if the work is allowed to proceed, the contractor obtains his experience at the expense of the corporation, and it may result that in the long run the corporation receives an article which is worth, as an investment, much less than would have been the case if another tender had been accepted even at a higher price. In the other instance—*i.e.*, that in which a consulting engineer passes by a low tender because he has no personal knowledge of the work carried out by the firm in question—we strongly support the grievance of the contractor. If tenders are advertised for, and a contracting firm goes to a great expense in sending in a tender with all the requisite drawings, it is not at all just that the tender should be refused because the consulting engineer has not taken the trouble to look up work which has been done by the firm for other towns or in other countries. We regret that this has been done in this country, and without doubt it will be done again; but, in our opinion, the only fair course for a consulting engineer to take if he means to only give the work to

Digitized by Google

certain firms who have carried out contracts for him before, is to advertise the fact on advertising the tender.

Lancashire Motor Trials.—The third series of trials of motor vehicles for heavy traffic organised by the Liverpool Self-Propelled Traffic Association, which is the local centre of the Automobile Club, direct attention to the important question of road haulage by motors. The first two trials under their auspices, it will be remembered, resulted in various improvements being effected, and as two years have elapsed since the last trial was made, a great difference was to be observed both in design and equipment among the entries for the trials which have been in progress during this week. These trials commenced last Monday with hill-climbing feats at Everton-brow, and manœuvring at Prince's Dock. On the following day the motor vehicles travelled with merchandise to Manchester *viâ* Warrington, and on the Wednesday they returned to Liverpool *viâ* Bolton. On Thursday the programme consisted of a run to Blackburn *viâ* Chorley, and the trials conclude to-day with the return journey *viâ* Preston. Thirteen vehicles are entered, and these are divided into four classes, carrying loads varying from 1½ to 5 tons. The firms represented are the Thorneycroft Steam-Wagon Company, Limited, the Lancashire Steam-Motor Company, Geo. F. Milnes and Co., Limited, C. and A. Musker, Limited, Mann's Patent Steam Cart and Wagon Company, Limited, T. Coulthard and Co., Limited, the Mechanical Transport Company, and Simpson and Bibby. The first days of the trials were marked by the entire absence of the breakdowns which were only too common at the earlier trials in the past few years. In the manœuvring tests within confined spaces all the vehicles behaved splendidly, and in the hill-climbing ordeals the results were also very gratifying, one of the wagons making the ascent in good style with a cargo weighing about seven tons. With regard to the long-distance runs, the motors behaved very creditably, and the results obtained may be regarded as highly satisfactory. Great interest is being shown in the tests, and several representatives of Government departments are watching the results.

Development in the Teaching of Physics.—Practical work is the all-important factor in the study of physics, and we are pleased to note that the development in the equipment of laboratories, etc., for the use of students receiving instructions in physics in the polytechnics has been exceedingly satisfactory within recent years. From an account of the progress made since the formation of the Technical Education Board, given in the *Technical Education Gazette*, it would appear that up to 1893 very little provision was made for practical work in the teaching of physics, the whole instruction being practically confined to lectures. Liberal grants, however, have from time to time been made for the equipment of laboratories and lecture rooms in the various institutions, with the result that at the present not only is there an enormous increase in the number of students receiving instruction in physics, but over 90 per cent. of these perform indlvidnal practical work having a definite relation to the theoretical instruction. As an example of this we may mention the well-equipped new laboratories of the South-Western Polytechnic, which were recently opened by Sir Wm. Preece. Among the other institutions which have been largely developed within the last few years are the Regent-street Polytechnic, the Birkbeck Institution, the City of London College, the Borough Polytechnic, the Woolwich Polytechnic, the Northern Polytechnic, and the Battersea Polytechnic. An important scheme is now under consideration for increasing the accommodation at the Northampton Institute. Every year marks a distinct increase in the number of students attending for instruction in physics and electrical engineering, the number attending these departments at the institutions referred to above being over 2,000 for the present session. A marked improvement is also to be noticed in institutions of lower rank than the polytechnics which are aided by the Board. Here also grants have been made for the equipment of laboratories, more efficient teachers have been appointed, and the instruction and conditions of working have improved considerably. In the secondary day schools aided by the Board much attention has been given to the rational teaching of elementary physics in connection with the general scheme of science teaching.

Development of Water Power in Canada.—A water-power development possessing some interesting features, and now being installed at Milleroches, Ont., is described in the *Canadian Engineer*. This company will take water from the Cornwall Canal, one of the St. Lawrence system of waterways, through a very short headrace, and will discharge directly into an old channel of the river itself. According to present proposals, the first development will provide for 4,000 h.p., under a head varying from 20ft. to 30ft. About 1,000 h.p. will be installed at once and used for lighting the Cornwall Canal and opening its locks, under contract with the Dominion Government. Power will also be transmitted to Cornwall, Ont., six miles distant. The benefit of such a supply to this place will be readily conceived when it is stated that it is solely a manufacturing town, the principal industries being the manufacture of cotton goods, woollen goods, and paper. Owing to the construction of a dam by the Government a few years back, the difference between the water in the canal and the water in the river at low water is nearly 38ft., and it is at this point that the present water-power development is being installed. A regulating weir was built here by the Government for regulating the height of water in the canal, which is kept at a minimum depth of 14ft. From the channel leading to this weir water will be taken in a headrace about 200ft. long, and after passing through the turbines will discharge into the bed of the old river channel laid dry by the building of the dam. Turning to the electrical equipment of the station, the generators to be installed are of the rotating-field type, of 750 kw. capacity, designed to deliver three-phase currents at 2,200 volts. There are two exciters, each of 50 kw. capacity, and either one is sufficient to excite the four generators which will make up the ultimate capacity of the station. The switchboard is to be of blue Vermont marble on an angle-iron frame, and provides for control of exciters separately or in multiple. Lead-covered cables will lead from the switchboard to the wire-tower on the second floor, in which will be located the station lightning arresters. The step-up transformers are to be installed on the first floor of the wire-tower, where the potential will be raised from 2,200 volts to 11,000 volts. The circuit wires fan out in both directions from the tower. Both the lighting and power lines are supported by cedar poles, spaced about 100ft. apart, every fourth pole bearing an alternating enclosed arc lamp. The three-phase 10,000-volt line is tapped at each lock for connection to a transformer, which steps the voltage down from 11,000 volts to 220 volts, the lock master's cabin serving as a small sub-station from which is distributed all the current for power service at the locks. The arc lighting and power cables for crossing from side to side of the lock terminate at the switchboard in the terminal or cabinet houses. The locks are provided with from six to thirteen lights, and motors are used for handling the sluice gates and for opening and closing the lock gates, as well as for control of the weir gates by

Digitized by Google

which the levels of the different sections of the canal are regulated. The use of electric light and power thus makes the canals quite as serviceable by night as by day, and practically doubles their capacity, besides handling the traffic more rapidly, permitting the boats to make more trips in a season, which tends to reduce the cost of transportation.

Glasgow Electricity Charges.—Subject to confirmation by the Town Council, the Glasgow Electricity Committee have fixed upon a scale of charges for electric current. Mr. W. A. Chamen, the Corporation electrical engineer, has prepared a report on the subject for the consideration of the Town Council, in which he states that the sum required in connection with the electric lighting undertaking for the year ending May 31, 1902, will be at least £92,000. The difficulty has been to decide on a scale of charges which would result in an increased revenue for next year. With this end in view the committee have arrived at these conclusions: (1) that it is unsound policy to reduce the initial price to one-hour consumers below the present rate of 6d. per unit, though they do not wish to increase it; and (2) that they will be more certain to obtain a largely-increased revenue through encouraging the sale of electricity to long-hour consumers by reducing the price to them. What are known as the "one-hour-and-under" consumers have cost £164,780 in capital expenditure to produce a revenue of only £6,208, or 3 7 per cent., while the consumers over one hour and upwards (excluding domestic, theatres, churches, and power), some 1,845 in number, have cost about £478,578 in capital expenditure, and produce a revenue of £46,154, or 9 6 per cent. The addition of short-hour consumers, therefore, is regarded as an increasing loss to the Corporation, even at the price of 6d. per unit. The actual average cost of about 6,000,000 units sold to private consumers during the past year is estimated at about 3 18d. per unit. If, with the estimated expenditure of £92,000 for this year, only the same quantity of electricity be sold, the average cost would be 3·68d. per unit. But should the sale of electricity increase by 50 per cent., as it has done for the past two years, the only additional cost would be for coal, and that would only be, at the most, some £6,000 for the extra 3,000,000 units, or a total expenditure of, say, £98,000 fer the 9,000,000 units, which would represent an average cost of 2·61d. per unit. With these facts before them, therefore, the committee considered that every effort should be made to sell 9,000,000 units during the year, and to this end that the price should be 6d. per unit for the first 365 hours of maximum demand, and 1d. for any further quantity, and that the rates for domestic consumers, theatres, halls, etc., should be 3½d. per unit; for churches, 3d. per unit; and for power, 1½d. per unit. The revenue produced on 6,000,000 units would be only about £72,000, but if, as anticipated, the output sold be increased to 9,000,000 units, and the proportions of the various class of consumers remain as at present, the revenue produced would be about £104,000, while, as before stated, the expenses would be about £98,000, leaving a balance of £6,000 to the good, and giving an average revenue of 2·77d. per unit sold. There can be no doubt that the policy of the committee as recommended by Mr. Chamen is the right one, as the reduction of the charge to long-hour consumers is sure in the long run to result in the more rapid growth of the undertaking, and consequently the swelling of the revenue. Any alteration in price on the wrong side would be sure to shake the confidence of the public, and would certainly not tend to an increase in the number of consumers of the right kind. In his report to the Town Council, Mr. Chamen gives it as his opinion that if the recommendation of the committee be accepted, there is no doubt whatever that the whole capital expended will be fully productive very soon, and in this view we entirely agree.

City and Guilds of London Institute.—We have before us the annual report of the council of the City and Guilds of London Institute as presented to the members at the general meeting held last month. The report opens with the statement (previously announced in this journal) that his Majesty the King has graciously consented to become patron of the institute, of which, as Prince of Wales, he has been president since 1881. On April 11 last year a petition was presented to her late Majesty the Queen in council for a charter of incorporation of the institute, which was granted. In the early part of last year the institute was offered 15 nominations to commissions in the army for students of the institute's colleges—10 in the Royal Artillery, and five in the infantry. An unaccountable delay occurred before any of the candidates were called up by the War Office for medical examination, until in August, before all the commissions were filled up, an intimation was received that a sufficient supply of officers had been obtained, and that it had, therefore, become necessary to close the offer to the technical colleges. Commissions in the army were, however, awarded to the following nine gentlemen who had been nominated—viz, Messrs. E. S. Allsup, T. C. Cunningham, D. G. W. Hume, F. G. Maunde-Thompson, H. R Scarlett, J. H. Stone, J. B. W. Stroud, C. E. Vines—all in the Royal Artillery—and W. L. Carter in the infantry, who has since resigned. In connection with the Central Technical College, the announcement is made that Prof. Henrici has been elected dean of the college for the session 1900-1. A table is given showing the course of instruction at the college, from which it appears that there has been a gradual increase in the number of students from year to year. In the year under review there were 281 students as against 245 in the year 1898-9, showing an increase of 36. At the close of the last session the diploma of associate of the institute was awarded to 46 matriculated third-year students. With regard to the Technical College at Finsbury, the council report that there was a satisfactory increase in the total number of students attending the college during the session ending in July, but attention is drawn to the fact that this was entirely due to an unusual increase in the number taking the electrical course, which increased from 64 to 101 in the course of the year. With this, however, there has been a slight falling off in both the mechanical and chemical departments. The fluctuation in the number of electrical students is also to be noticed at the Central Technical College, although not to the same extent. The council regard this state of things as being in all probability due to the varying prospects in public estimation of the electrical industries The rapid development of electric traction in this country during the past two or three years has no doubt attracted an increasing number of students to the electrical departments, and very possibly at the expense of the others. At the close of the session certificates were awarded to 56 students, as against 38 in the previous year; 9 in mechanical engineering, 29 in electrical engineering, and 18 in chemistry. There was a small increase in the number of students entering the South London Technical Art School last session over that of the previous session, and the work done continues to be of an earnest and satisfactory kind. In the technological examinations department there has been a further growth in the work of the department during the past session, and in the other branches of the institute similar progress is reported.

TYNEMOUTH ELECTRICITY WORKS.

Tynemouth, which has been for years the health resort of Newcastle-on-Tyne, will this summer have the additional attraction of electric light in its main streets, and also of electric traction to enable visitors to get to Whitley and Cullercoats easily. The electric lighting is in the hands of the Corporation, and from the same works a supply of electrical energy is given to the tramways, which are being worked by a company. The area of the borough of Tynemouth is much more extensive than would be expected from those who have only gone to Tynemouth for pleasure, as it includes a large part of what would be thought to be North Shields. The population of the borough is about 50,000.

MR C. TURNBULL, BOROUGH ELECTRICAL ENGINEER OF TYNEMOUTH.

JACOB DAGLISH, ESQ., MAYOR OF TYNEMOUTH.

R. IRVIN, ESQ., CHAIRMAN OF THE TYNEMOUTH ELECTRICITY WORKS COMMITTEE.

The electric lighting provisional order was obtained by the Corporation in 1891, but no steps were taken to put the powers of the order into force until 1895. The Corporation then circularised the inhabitants to know how many would take the electric light if a supply were given. The results of this enquiry were as unsatisfactory as similar enquiries have been in other towns. The inhabitants refused to give answers which they thought would commit them to take the supply. In consequence of this, the matter was again shelved until 1897, when Mr E. M. Lacey (of the firm of Messrs. Lacey, Clirehugh, and Sillar) was retained to advise the Corporation. The question of electric traction was then under consideration, and under his advice a combined station for supplying electric light and electric energy for the tramways was laid down.

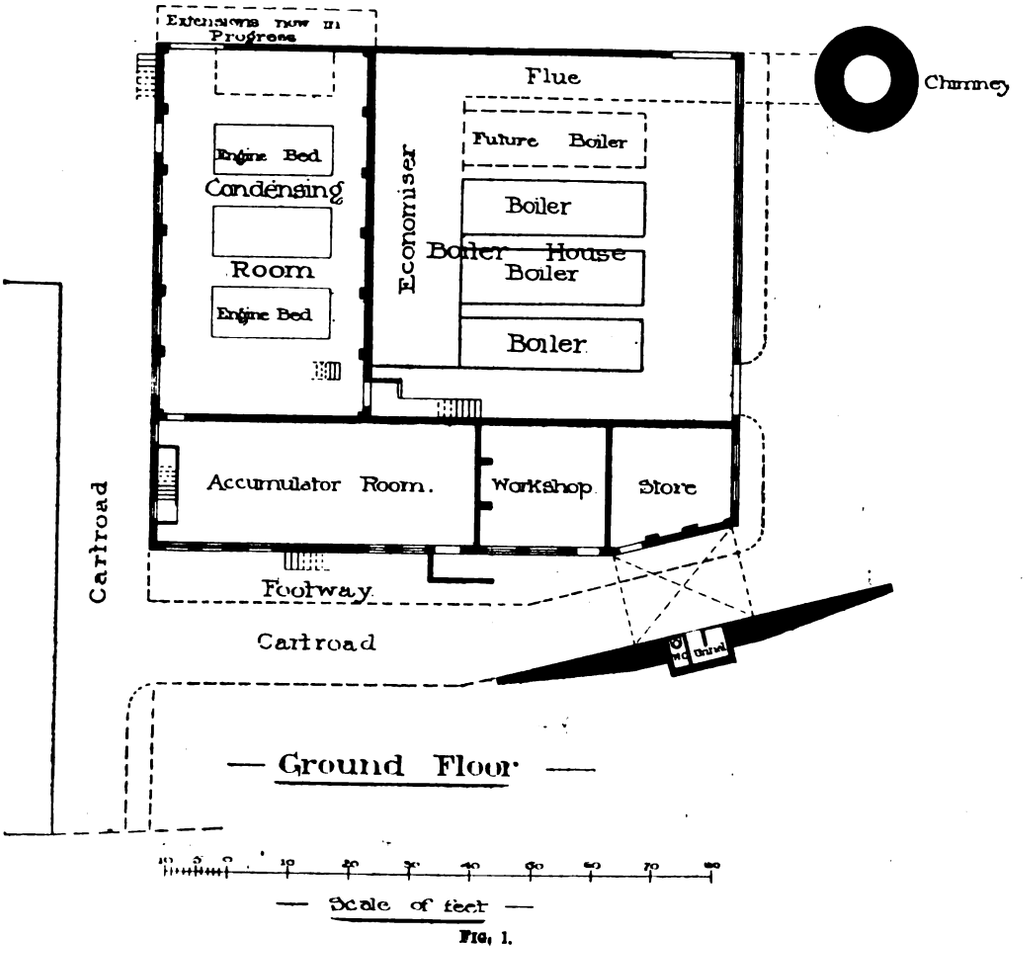

FIG. 1.

Digitized by Google

As a result of the combination, Mr. Lacey was enabled to increase the size of the plant provided in the first instance. A good site was obtained, practically in the centre of the area to be supplied, from which distribution by means of direct currents could be conveniently carried out. The site is situated in Pow Dene, which is only a short distance from the Tynemouth goods station, from which coal is obtained. The consulting engineers and Mr. John T. Smillie, the borough surveyor, have made most excellent use of the characteristics of the site selected. The area which is at the bottom of the Dene adjoins on to the road which leads up the side of the Dene into the main Tynemouth road. The works being at a considerably lower level than this road, arrangements have been made to enable the coal to be brought in at a high level and shot directly into the coal bunkers over the boiler-room, which holds 300 tons of coal. In Figs. 1 and 2 we give the first-floor and ground-floor plan of the works, and in Fig. 3 is shown the front elevation of the works and offices. The bridge, which is seen at the right hand of the illustration, is used for bringing in the coal, and it will be seen how much higher this is than the level of the boiler-house floor.

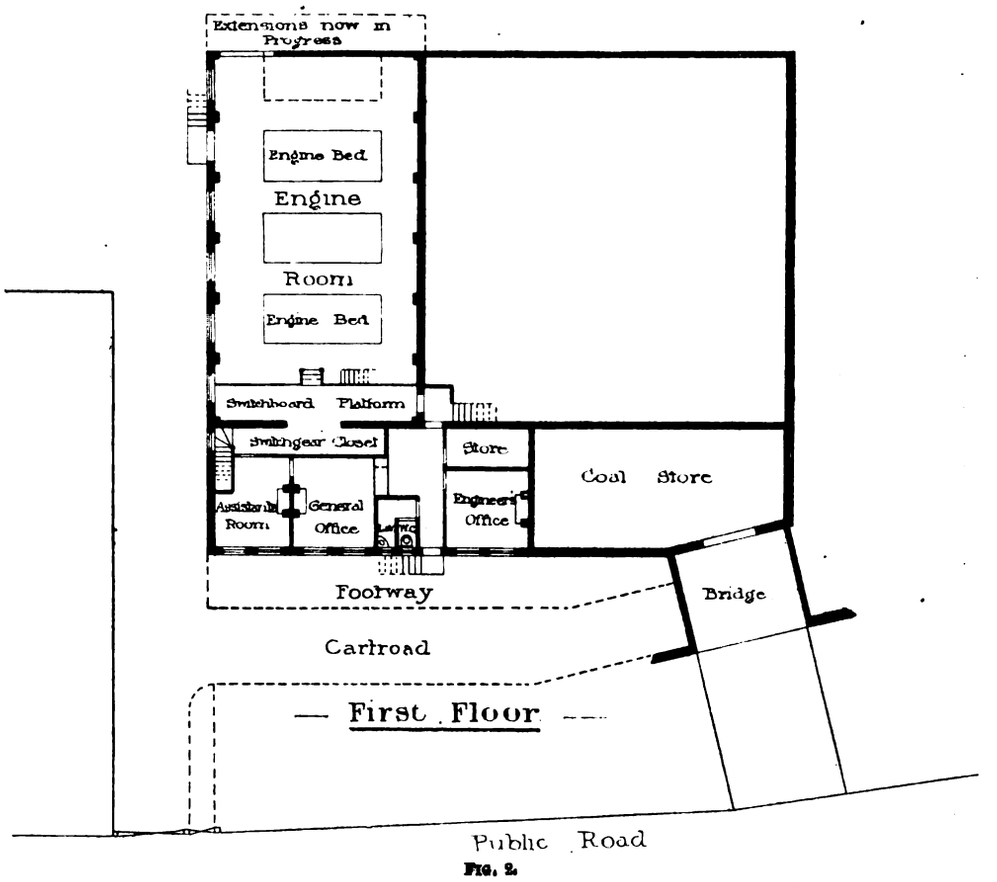

FIG. 2.

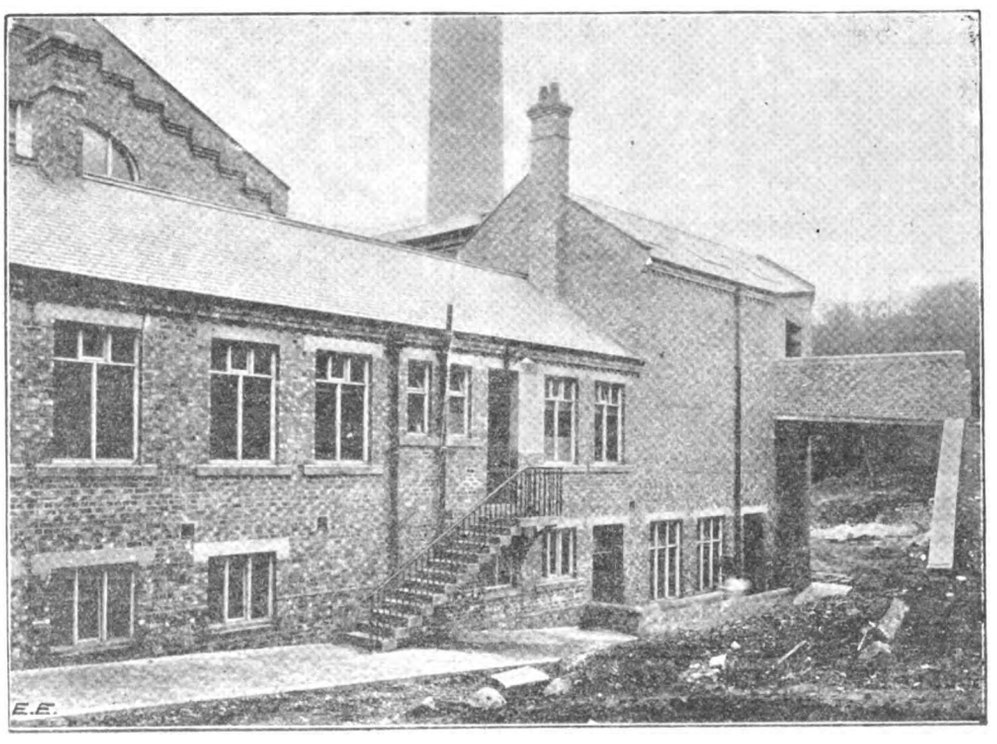

FIG. 3.—View of the Offices and Boiler-House of the Tynemouth Electricity Works.

In planning the buildings it was sought to make supervision over each department as easy as possible. Upon the lowest and at the same level are the boiler-house, the room for condensing plant, the accumulator room, the workshop,

Digitized by Google

and store. At a higher level, over the condensing plant room, is the engine-room, and at a height of 2ft. 6in. above that and over the accumulator-room are the offices. The switchboard platform and the offices are on the same level. The offices are approached by an outside stair, the object in placing it outside being to preserve an unbroken area in the accumulator-room. The buildings are entirely of brick, the engine-room being glazed from floor to roof with glazed brickwork. The whole of the floors, excepting those in the offices, which are of wood, are of cement concrete, the surface of the engine-room floor being finished with tiles. The chimney shaft is circular in plan, and is 150ft. in length above the ground level, the foundation being carried 20ft. below. The internal diameter is 8ft, and it is intended to serve the proposed refuse destructor as well as the electrical plant. These buildings were all designed by Mr. Smillie, who also superintended their erection.

The steam-raising plant now installed consists of three Lancashire boilers, which were supplied by Messrs. Yates and Thom. These boilers (Fig. 4) are each 30ft. long and 8ft. 6in. diameter. They are designed for a working pressure of 150lb. per square inch, and are guaranteed to evaporate 8,000lb. of water per hour. These boilers are fired by means of Proctor sprinkling stokers, which can be seen in Fig. 3. The main coal bunker is situated at the farther end of the boiler-house, and runs transversely across it, as can be seen in the above-mentioned illustration. The coal from this main bunker runs by gravity into a conveyor placed under it. This conveyor delivers into the second conveyor, which is seen in the front of the boilers over the stoker hoppers. These two conveyors were supplied by Messrs. Graham, Morton, and Co., of Leeds, and are each driven by electric motors made by the Clayton Engineering Company. The great reduction in speed required is obtained by worm gearing, while the thrust of the worm is taken on ball bearings. The stokers are also driven by an electric motor. At the back of each of the boilers are placed Musgrave superheaters, which are designed to give a superheat of

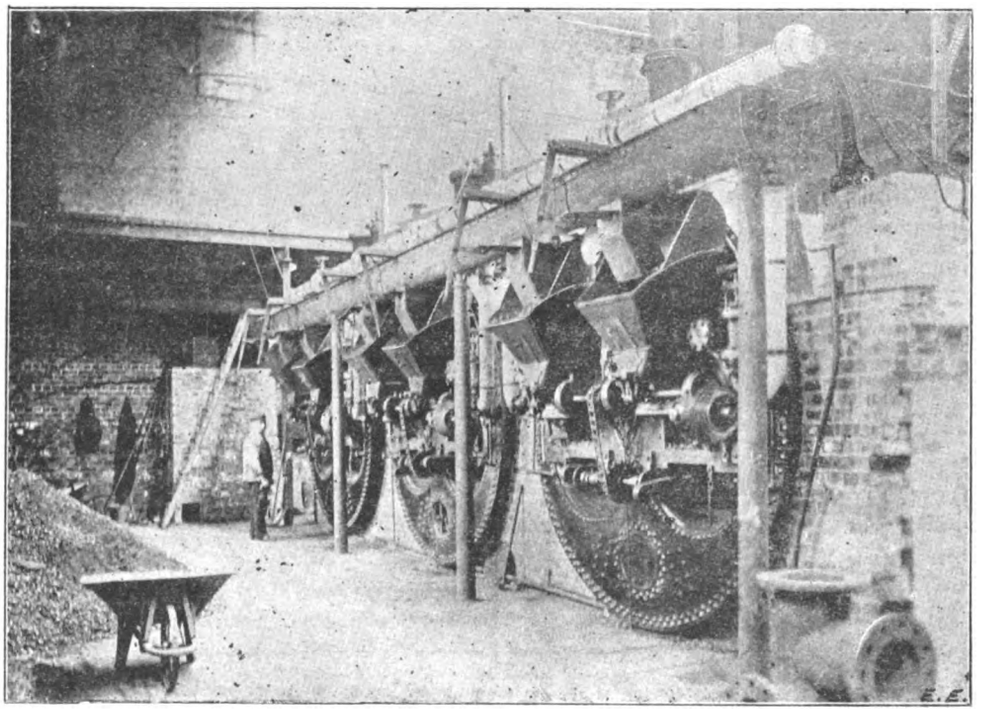

FIG. 4.—Yates and Thom Boilers and Proctor Stokers in the Tynemouth Electricity Works.

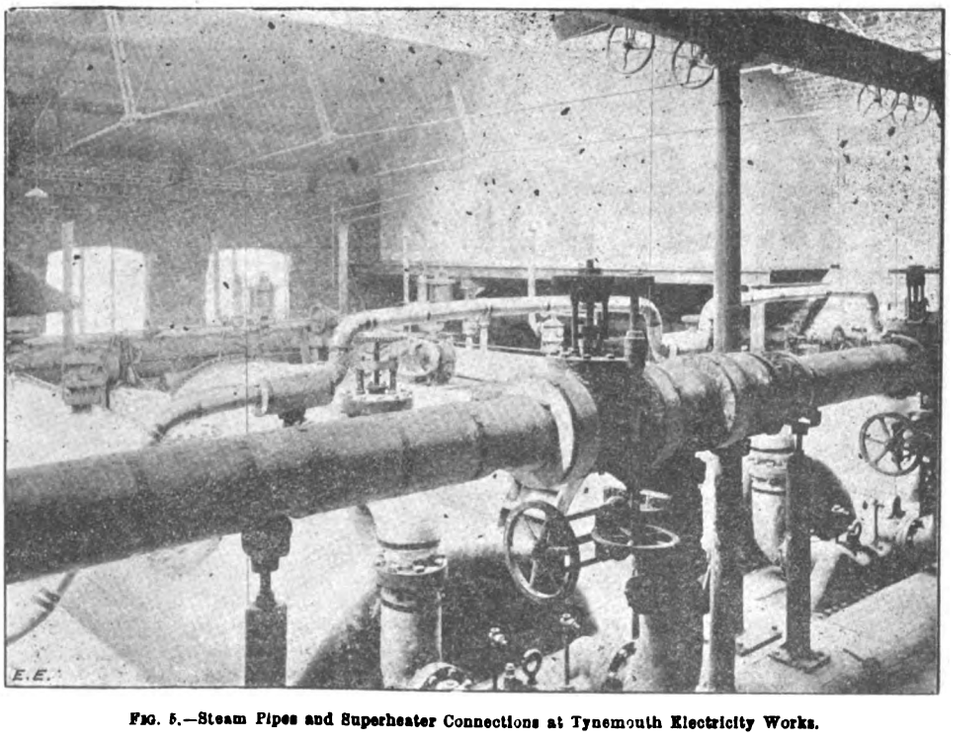

FIG. 5.—Steam Pipes and Superheater Connections at Tynemouth Electricity Works.

Digitized by Google

20deg. to 150deg. at the stop valve of the engine. The connections to these superheaters can be seen in Fig. 5. In each case a by-pass is arranged, so that the whole of the steam given off by a boiler need not be passed through a superheater. In this way the degree of superheat can be varied. The boilers are fed on a system which allows a complete duplication, so that the breakdown of one part of the feed pipes, or of one feed pump or one injector, will not interrupt the supply of feed water. Two electrically-driven three-throw pumps, by Messrs. Goddard, Massey, and Warner, have been supplied, each capable of delivering 2,500 gallons of water per hour against the full boiler pressure. These electrically-driven pumps are controlled on the series-parallel system, so that their speed can be varied from full to one-quarter of full speed in easy steps. In this way a continuous feed at all loads can conveniently be obtained. In Fig. 6 is shown a section through the station from which a general run in the levels of the steam-pipes can be gathered. The main ring is 9in. in diameter, and is equipped with Hopkinson valves, so that any length can be isolated for repairs.

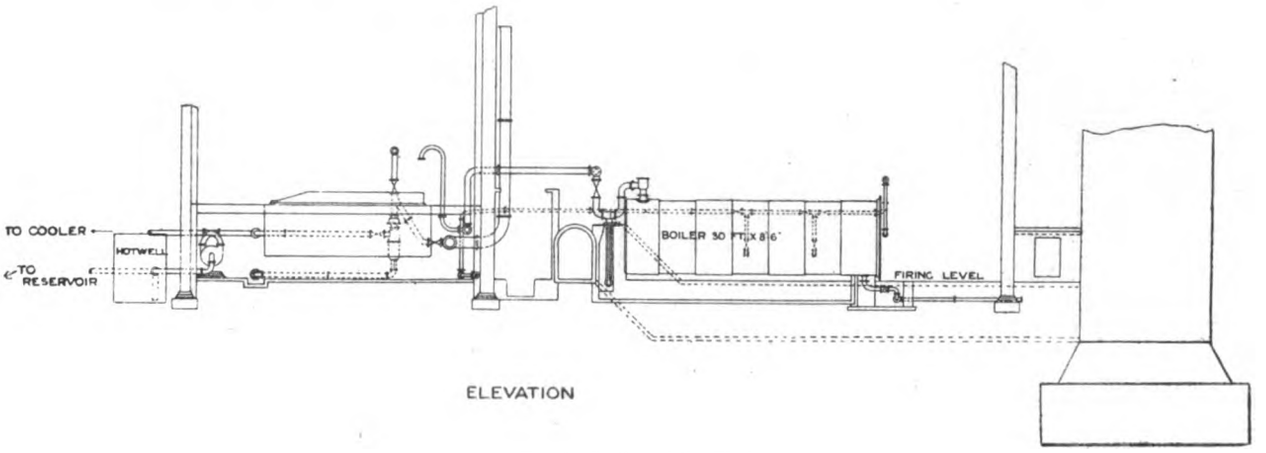

FIG. 6.—Section of the Works.

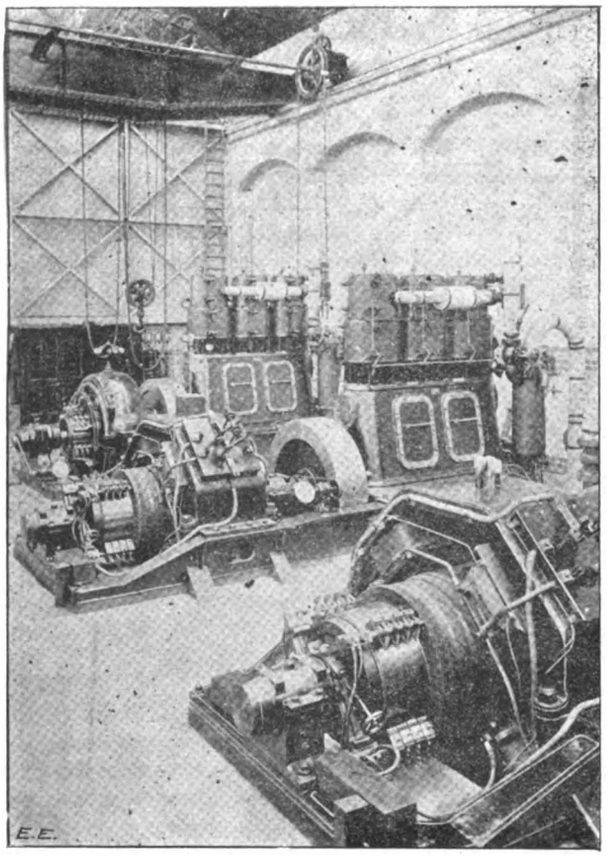

FIG. 7.—View of the Tynemouth Generating Plant.

The engine-room plant consists at present of three Belliss engines, each capable of giving 300 i.h.p. at 420 revolutions per minute. The engines are of the six-cylinder compound type, driving on to three cranks spaced at 120deg. apart. The governing of these engines is so arranged that in the event of a sudden heavy load high-pressure steam is admitted into the low-pressure cylinders, in which case the engines are able to give 360 i.h.p. In Figs. 7 and 8 a general view of this engine-room can be obtained. The first two engines from the switchboard end of the building are directly coupled to two dynamos, supplied by Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne. These are of the four-pole Lundell type, made as described in our last issue, and are nominally 180-kw. machines. They are specified to give 360 amperes at any voltage from 445 up to 500 when working on the shunt, or up to 550 volts when the series coils are in circuit. From the results obtained on trial, however, we gather that these dynamos are very considerably under-rated, as they are capable of giving much higher loads than mentioned above under the specified conditions. These two machines are normally intended to take the lighting load, but throw-over switches placed on the machines, as seen in Fig. 7, enable them to be quickly transferred to the traction side of the station. A spare armature has also been supplied for these two machines. The third dynamo, which under ordinary conditions will take the traction load, is of the Westinghouse type, and was supplied by the British Westinghouse Co. This dynamo is seen in the foreground of Fig. 8. It is of the six-pole type, and is nominally of 190 kw., being able to give 380 amperes at from 490 to 550 volts. The regulation of the compounding of this machine is effected by means of a variable shunt across the series coil. In laying down all the above plant, Mr. C. Turnbull, the borough electrical engineer, was careful to get the foundations excellently level to start with, so that practically no grouting was required.

The exhaust from the engines can either be taken into a main exhaust pipe to atmosphere, or condensed in Ledward ejector condensers. One of these ejector condensers is supplied for each engine. The water coming away from the same is led to a hot-well, and from thence is forced up to the top of a cooling tower supplied by the Klein Engineering Company. This tower occupies a space 35ft. by 24ft., the top of the chimney is 60ft. high, and the water inlet is placed 25ft. up. The capacity of this water-cooling tower is guaranteed by the makers to be such as to be able to cool the water from engines developing 1,000 h.p. Two electrically-driven centrifugal pumps are used in connection with the condensing plant, the one for circulating the water to the condensers, and the other for raising the hot water to the top of the cooling tower. Each of these centrifugal pumps is driven by a Royce motor. The pumps are placed in the basement. In Fig. 9 we show the circulating pump, and also the automatic controlling gear for stopping the lifting pump when the water in the hot-well falls below a predetermined level. This automatic gear consists of a rocking lever, along which a heavy weight can roll. This rocking lever is seen in the illustration behind and just above the coupling of the circulating pump. The axis of the lever is taken through the engine-house wall, and on it is then connected another lever, terminating in a float in the hot-well. In the

Digitized by Google

position shown in the illustration the motor is not connected. When, however, the water in the hot-well rises, the lever will rock until the rolling weight, seen to the left, is raised above the axis of rotation of the lever. The weight then runs down and closes the switch quickly by means of the vertical connecting rod seen in the illustration. The switch gear is placed on the engine-floor level to one side of the water-level gauge.

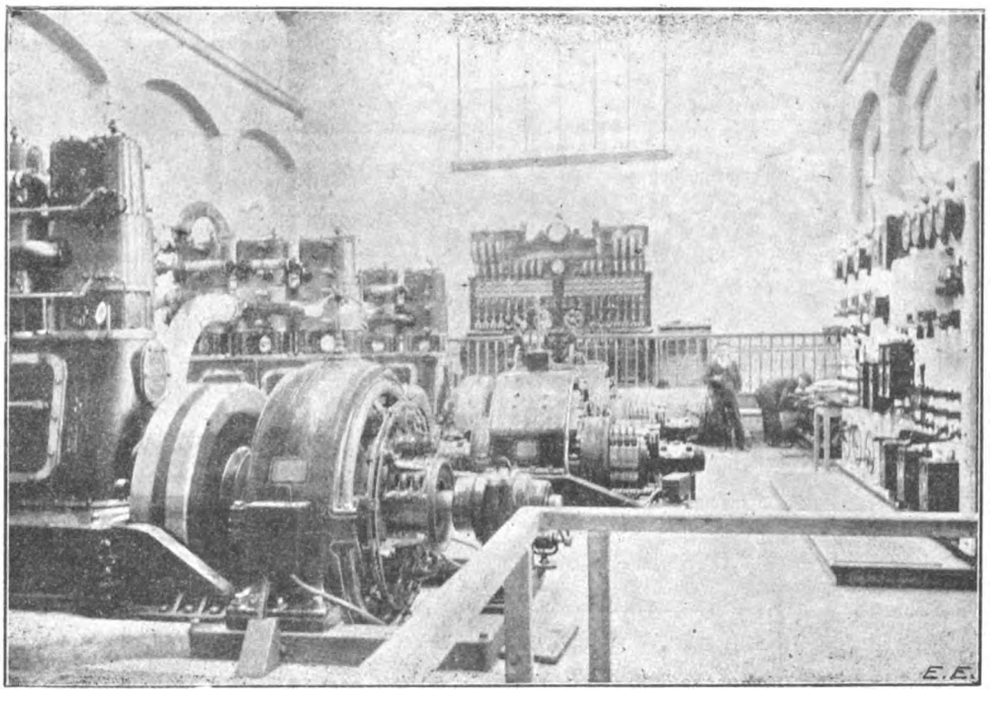

FIG. 8.—General View of the Tynemouth Engine-Room.

space would be advantageous. The main fuses come rather close to the main switch and omnibus bars, and may cause trouble in the event of a short-circuit on the mains. The instruments are all of the edgewise type, so arranged that they can be conveniently read from the engine-room floor level. The traction switchboard is of the Westinghouse standard type (as will be seen from the illustration, Fig. 12), while Fig. 13 gives the connections used in this

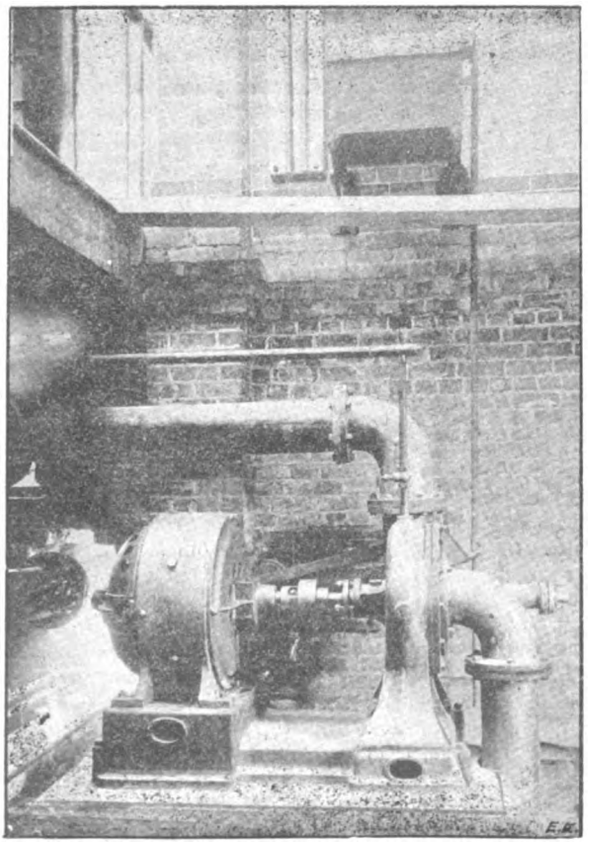

FIG. 9.—Electrically-Driven Circulating Pump and Automatic Contact for Lifting Pump.

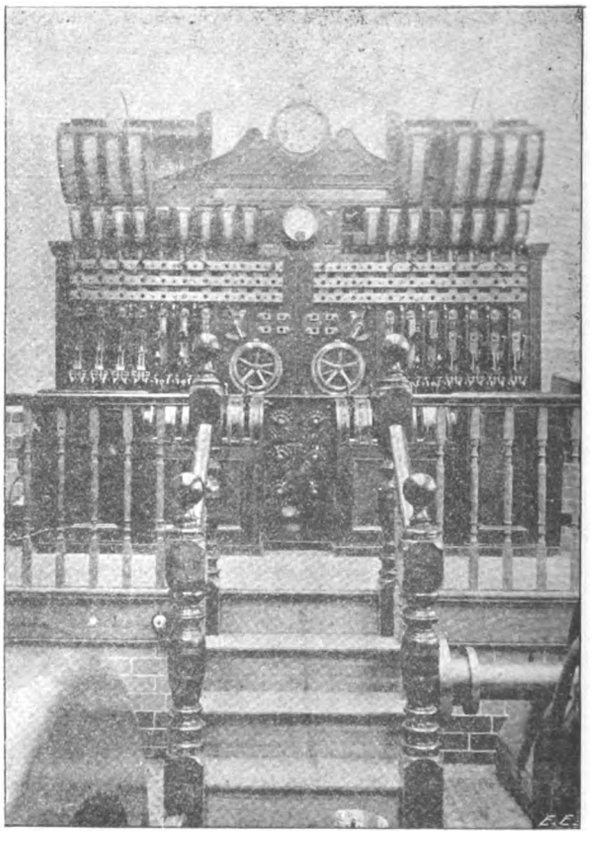

FIG. 10.—The Lighting Switchboard at Tynemouth.

The lighting switchboard is shown in Fig. 10, while Fig. 11 is a diagram of connections used. This board was manufactured and supplied by Mr. Bertram Thomas, of Manchester, and it will be seen that a very compact board has been obtained—in fact, we think that a little more case. The tramway company takes its supply from terminals behind this board.

The accumulators are of the Pritchetts and Gold standard type. There are 252 cells altogether, with a normal discharge of 60 amperes for 10 hours, or 250 amperes

Digitized by Google

for one hour. They are fixed in lead boxes in a well-lighted accumulator-room.

The mains were all supplied and laid by Messrs. Siemens Bros. and Co., and are of their armoured type, laid direct in the ground. When putting the cables down, however, pipes were laid in certain places, through which additional feeders can be drawn in at a later date. Four feeders have at present been laid. The first of these goes to the east end of Front-street, at Tynemouth, where it is terminated in a feeder pillar opposite the Tynemouth Priory; the next feeder terminates at the junction of Albion-street and Church-street; the third feeder at the junction of Saville-street and Bedford-street; while the fourth feeder is arranged to supply the riverside premises. All the best residential streets and business thoroughfares have already been supplied with distributing cables. In some cases what we believe is a novel procedure is adopted, as instead of running the cables down each side of a resi-

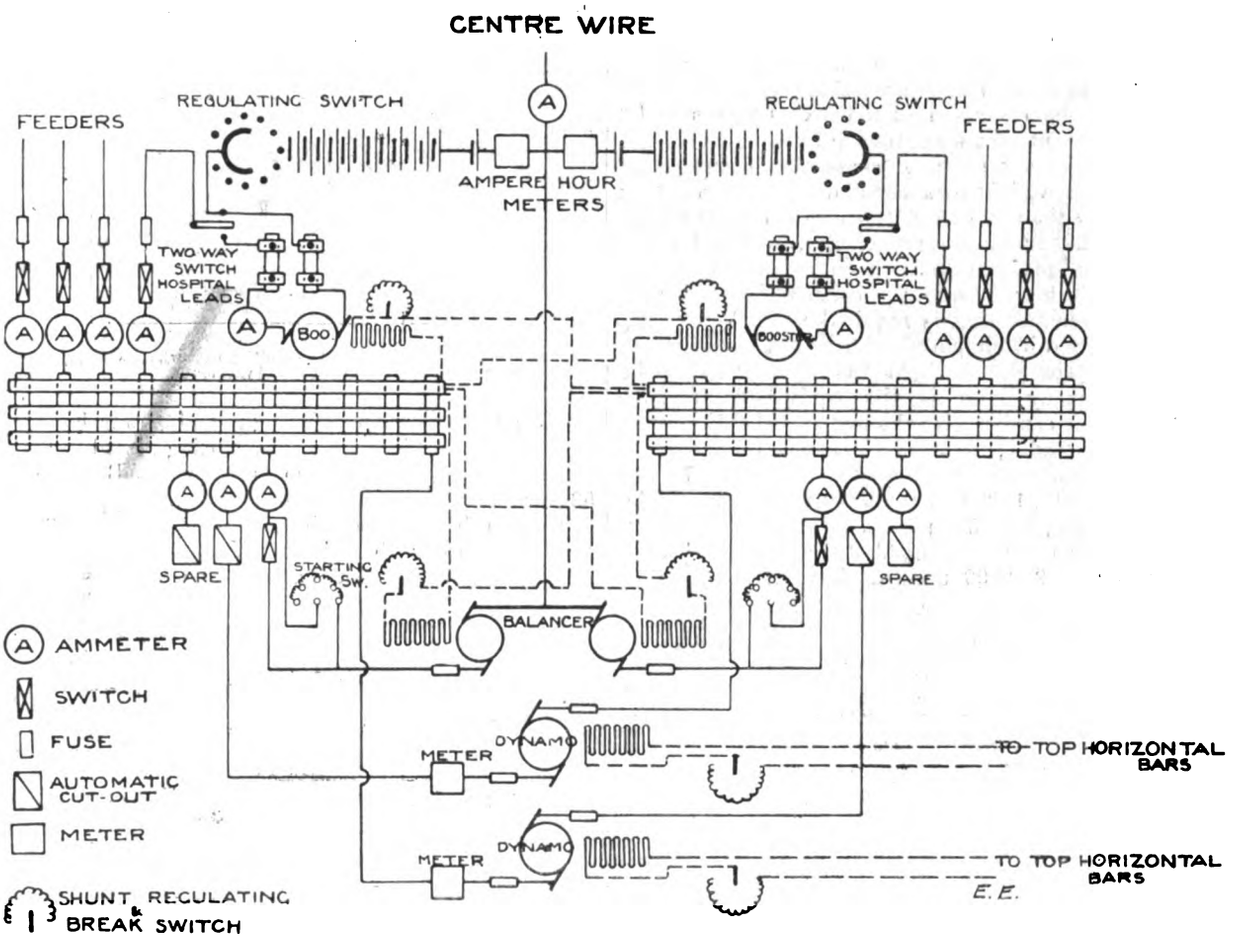

FIG. 11.—Diagram of Lighting Switchboard.

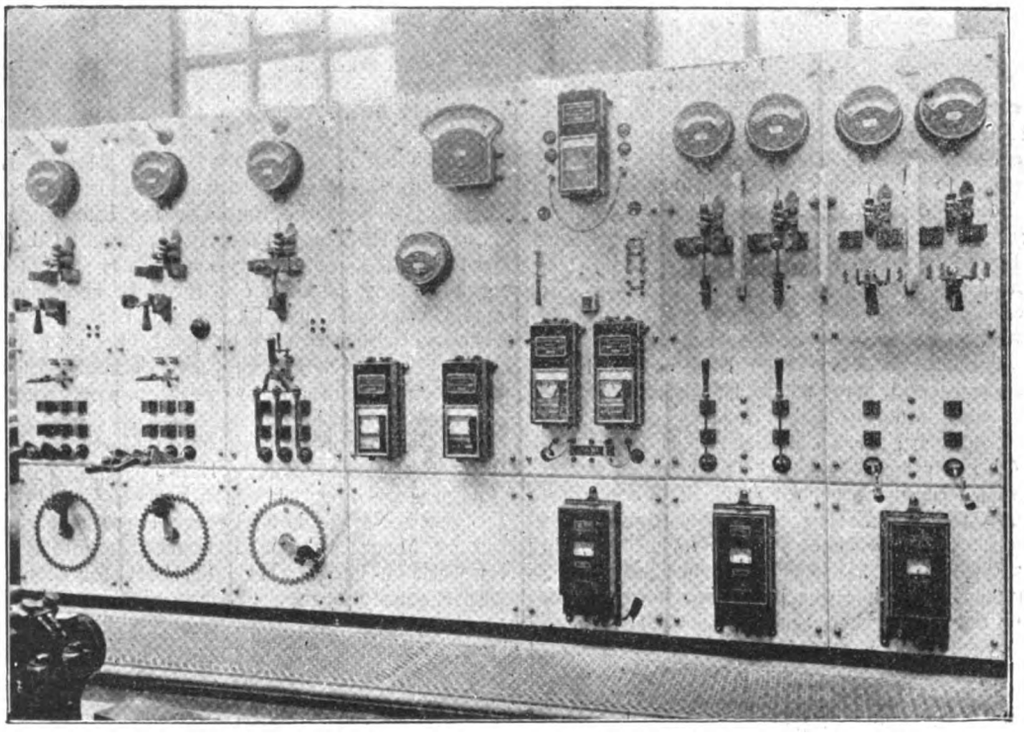

FIG. 12.—View of the Westinghouse Traction Board.

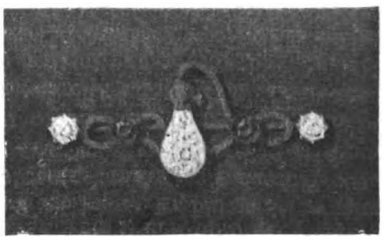
Digitized by Google

dential street, a single cable is laid in the back lane between two such streets. Mr. Turnbull informs us that he finds it cheaper to make the connections from such cables than from cables in the main street, and that it saves in cost in the first instance. Also it is more convenient to have the meter in the kitchen than in the front of the house. As regards the middle-wire connection, this is earthed at the station through a fuse in parallel with a suitable resistance. This resistance is to be composed of a bank of lamps. Mr. Turnbull informs us that when testing for lengths on the main, he arranges a temporary connection between the positive and negative 'bus bars at mid-day or on a Sunday; he then connects the one end of the one-half of the main battery to earth through a galvanometer, so that he gets the record of the total leak to earth on the whole system. Having obtained this, and also the earth leakage on each side of the system, all that is required to be known can be readily obtained by simple addition and subtraction.

The demand for electric light has been found to be good; thus already there is the equivalent of some 8,000 8-c.p. lamps connected to the mains, and this number will soon be exceeded, as a good demand for motors is arising. The consumers are charged at the rate of 7d. per unit for the first 100 hours' use per quarter of the maximum demand, and 2d. per unit for all above this. The tramway company are charged at the rate of 1½d. per unit for the first 200,000 units used per annum, with a minimum payment guaranteed of £1,100 per annum. For any excess of current used over the above quantity per annum, a reduction is given in the following way: for the next 50,000 units, 1·4d.; for the next 50,000 units, 1·3d., and so on until 400,000 units per annum is reached, after which the fixed charge will be 1d. per unit. At present some 12 arc lights only have been fixed as a kind of experiment in street-lighting. These lamps are of the Siemens type.

The Corporation, to encourage consumers, have entered into an arrangement with the Northern Electric and Engineering Company, a local firm, to do free wiring at the following rates: for one fitting with one lamp and switch, 3d. per lamp per quarter; for an additional point on the same switch, 4d.; for an additional lamp on a fitting without a separate switch, 3d. per quarter. The consumer can hire-purchase the installation by paying double the rent for 4½ years, or 1½ times such rent for 6½ years. Up to the present date there has been such a demand for ordinary consumers that it has not been possible to push this system very much, but there is every reason to believe that it will prove to be a useful means of attracting consumers.

The official opening of the works took place on April 3 last, but at that date they had been running for about six weeks. The ceremony was of a semi-private nature, as it was not considered advisable to have too many people about when some of the machinery was, of necessity, running for the trams. The Mayoress of Tynemouth (Mrs. Jacob Doglish) started the engine, and was presented by the Chairman of the Electricity Committee with a diamond brooch in commemoration of the occasion. This brooch was designed, to the instruction of the engineer, in the form of an electric lamp (diamonds) in a gold holder, and was very effective.



The Brooch presented to the Mayoress when switching on the light at Tynemouth.

The extensive demand for light and power has already necessitated orders for more plant being placed. Thus the consulting engineers inform us that a Bellias-Siemens 520-kw. steam dynamo is now on order. The boiler plant is also to be increased by another 30ft. by 8ft. 6in. Lancashire boiler by Messrs. Yates and Thom. The condenser and pipework for the new plant extensions will be carried out by Messrs. Hedley and Boyd, of North Shields.

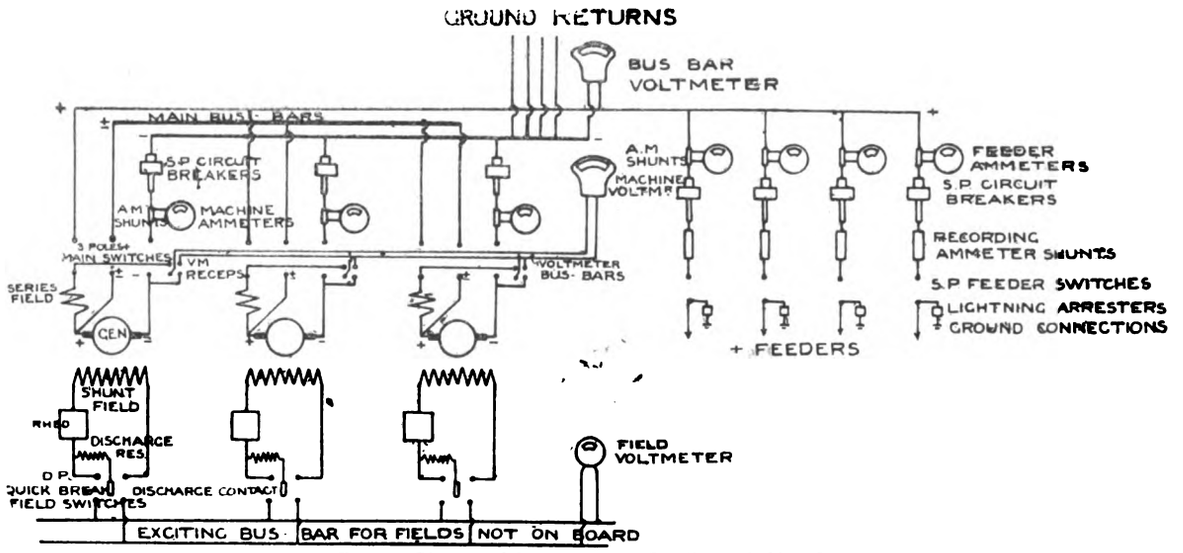


FIG. 13.—Diagram of Connections for Traction Switchboard.

In conclusion, we have to thank Messrs. Lacey, Clirehugh, and Sillar, the consulting engineers, and Mr. J. F. Smillie, the borough engineer, for kindly placing information and drawings at our disposal, while Mr. C. Turnbull was most kind in showing us round the station and explaining the many details of interest in connection with the same. We think that Tynemouth has an electric lighting station of which it may be justly proud, and which will enable electricity to be supplied at rates satisfactory both to the consumers and to the ratepayers, who guaranteed the requisite capital.

Mr. C. Turnbull, the borough electrical engineer, was educated at Fettes College, Edinburgh, and afterwards had a business training. He then went to the Durham College of Science, Newcastle-on-Tyne. He served his apprenticeship at Messrs. C. A. Parsons, Steam-Turbine Works, Newcastle-on-Tyne. He left them for the Scarborough electric supply station. Before coming to Tynemouth he was for some time with the National Electric Wiring Company as district manager.

Liverpool.—Another electric wire accident occurred in Liverpool last week. While a car was turning a sharp curve leading from Tithebarn-street into Moorfields the trolley jumped the wires, and becoming entangled with the overhead arrangements, brought down a number of wires on top of the car. There were no personal injuries.

LEICESTER TRAMWAYS.

Through the kindness of Mr. E. G. Mawbey, M.I.C.E., the borough surveyor of Leicester, we are able to produce this week a map which shows clearly the routes of the proposed electric tramways in Leicester. On this map the existing tramways are shown by thick black lines, while the dotted lines indicate the proposed extensions. The boundary of the borough of Leicester is indicated by a black line which is shaded on the inside. On this map is also shown the positions of the two sites for the generating works. The first of these is indicated by the black concentric circle near the upper part of the map. It is this site which is recommended by Mr. E. Manville, of the firm of Kincaid, Waller, and Manville, the consulting engineer to the Leicester Corporation. It will be seen from an inspection of the map that the position of this site is a fairly central one, also as practically all the extensions are being made to the north of the town, it tends to become more central. It is also close to those routes on which the heaviest traffic will occur. The other site, which is shown in the lower part of the map, is situated at the gasworks. It will be seen that this is some considerable distance from the centre of the town. Mr. Manville has advised the Corporation that a direct-current

supply at about 500 volts could be given to all the tramways if the first site were used, whereas if the tramway generating plant is placed at the gasworks a polyphase high-tension transmission scheme would be required.

THE COMING VISIT OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO BERLIN.

Among the establishments to be visited in Berlin by the Institution of Electrical Engineers the world-renowned works of Messrs. Siemens and Halske are of the first importance. Probably no better proof of the phenomenal progress made in electro-technical science can be obtained than by following the remarkable growth of this firm, which was established by Werner Siemens and T. G. Halske over 50 years ago. At the World's Fair in London, 1851, the improvements made by the firm on the Morse telegraph were rewarded by the council medal, which was conferred on but a few exhibitors. From that time the business of Messrs. Siemens and Halske, owing to the enormous development of electricity, grew steadily, and the firm found it necessary to establish new branch factories in different parts of the city and suburbs.

At present the works of Messrs. Siemens and Halske consist of the following establishments at and near Berlin: (1) the Berlin works in the Markgrafenstrasse, telephones, telegraphs, measuring instruments, etc.; (2) the dynamo works at Charlottenburg; (3) the cable works at the Nonnendamm, between Charlottenburg and Spandau; (4) the incandescent lamp factory at Charlottenburg, Helmholtzstrasse; (5) the block works (railway safety appliances) at Charlottenburg, Helmholtzstrasse, now in course of construction, to be opened in August, 1901.

The Berlin Works of Messrs. Siemens and Halske.

A bird's-eye view of these works is shown in Fig. 1. The building in the Markgrafenstrasse (Fig. 2), which was purchased over 50 years ago by Messrs. Siemens and Halske, has up to the present day been intimately connected with the development and growth of the concern. It is still considered the centre of the whole works, even though other large factories have been established by the firm. But the reader must not suppose that this building, similar to palatial factories, now built with long stretched fronts, high, broad windows, splendid façades, and elaborate decorations, in its whole external appearance gives a picture of the size and extent of the whole plant. The house which one enters is not modern, but it has something not possessed by new establishments—namely, a historical importance.

It is not our purpose to enter in detail on the gradual rise of the parent building, for it can be of but little interest to the reader to learn how from time to time the neighbouring buildings were purchased and connected with the above-named centre, or that even in neighbouring streets a number of factories and workshops, as, for example, the huge works in the Lindenstrasse or the screw factory in the Markgrafenstrasse were established. Yet all these extensions for a length of time could not satisfy the growing demands for more room, and so a large building is now being erected at the Ascanischeplatz intended for the "Central-Abteilung," the managing department of the firm, and for the electric railway department, both of which have remained till now in the parent building. It can be well understood that with the increasing growth of the Berlin works its enlargement could not be uniform, and the sketch (Fig. 3) showing the extended factory yard also indicates how gradually one factory building has been added to the other. Originally the two side buildings in the foreground were used for factory purposes. Later on the five-storeyed factory building in the left background was added, becoming the home of the first cable-works in Germany, in conjunction with the opposite building. The two side buildings in the background were next added, and finally the connecting cross building, which fronts upon the Charlottenstrasse. From a practical point of view, the engineer will hardly look at this narrow yard with an admiring eye, but when he considers the past, and looks from the designing table and out of the workshop beyond to the past history of electro-technical science, if he comprehends the present time in its whole fulness and realises the importance of technics in modern political economy, he will bring his mind to bear on the thought that this plain, narrow piece of earth, this simple factory yard, crowded with wagons and goods, is the point of departure of a great deal of the progress in modern electricity.

We will not attempt to make a description of the different lines of manufacture carried on, as the Berlin works devote themselves exclusively to the production of small and fine apparatus in the line of the mechanic, an account of which would be of little interest to the reader. In its place will be given a short account of the different factories which comprise the Berlin works. At first, telegraphy should be mentioned as the oldest business of the house. This department comprises a number of sections. Many of these form factories in themselves, as, for example, the making

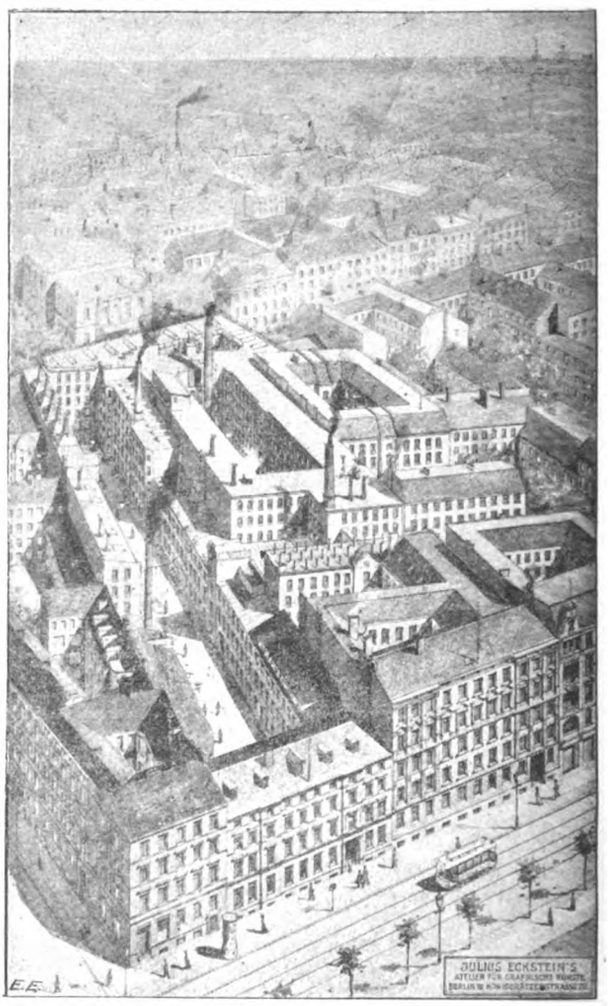

Fig 1.—Bird's-eye View of the Berlin Work.

of the Morse apparatus, of the printing, telegraph, and railway signalling apparatus. The same can be said of the manufacture of measuring and controlling instruments, as also of the department of accessories for telegraphic plants of every kind. In order to give an idea of the extent of the whole operations, it may be mentioned that in the telegraph and telephone departments about 5,000 different kinds of articles are made. The second main section of the Berlin works comprises the telephone department, which produces microphones, telephones, annunciators, and, finally, the well-known telephone apparatus of the firm's make. The latter have attained an exceptional importance, and were awarded with a "grand prix" at the Paris Exhibition in 1900. Further, the section of measuring instruments deserves to be mentioned. Its importance may be recognised by the fact that the measuring instruments of Siemens and Halske—as, for instance, the Universal galvanometer—have found their way to all parts of the world. What distinguishes this

Digitized by Google

department from all others is the fact that it requires not only the skilled hand of the mechanic, but also the scientific training required for the examination of instruments. The workshops where the latter are made also contain adjusting rooms, where the instruments are most carefully examined and calibrated. The fourth factory belonging to the Berlin works is the one devoted to railway safety appliances, whose construction frequently serve as models for others, and have also rendered possible,

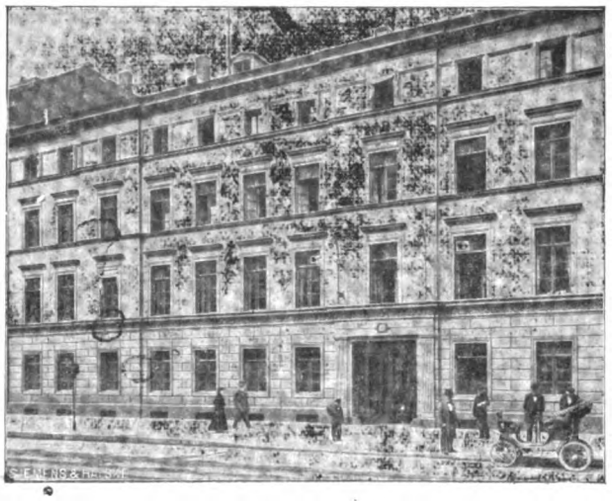

FIG. 2.—Front View of the Berlin Works, Markgrafenstrasse.

regular, and safe the fastest train service. Now, this department, owing to want of room, will be transferred to Charlottenburg. The fifth section, the manufactory of water-meters, has nothing to do with electricity, but is intimately connected with the name of Siemens, as William Siemens was the inventor of the water-meter. The sixth and youngest department is one for the manufacture of articles of precision. This section, however, is not, like the others, divided according to the articles manufactured, but

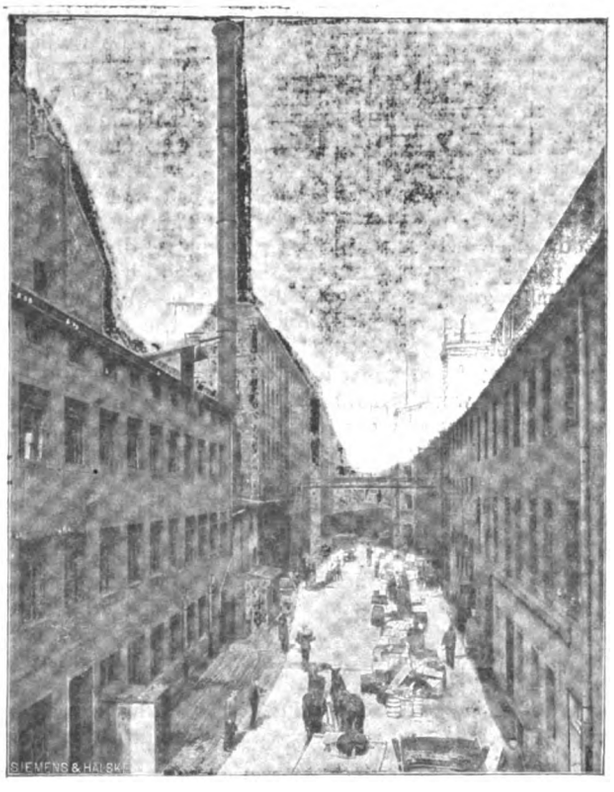

FIG. 3.—Factory Yard.

makes them all. It is well known that the firm from its very early beginning has aimed to make apparatus perfect to the smallest detail. Formerly this could only be attained by the carefully trained and skilled mechanic, but such a division of labour was not only expensive, but also unprofitable and took much time.

In the course of the last decade of the nineteenth century a new method for the making of metallic parts was developed, the whole work consisting of a series of the simplest steps, a machine constructed especially for this purpose being used for every step in the manufacture. The machine executes the work with great exactness, and therefore, with its aid, every part of the article to be made can be produced in large quantities and at a cheap price, as the machine needs only careful supervision by an experienced workman. Yet this achievement in the construction of machines has only gradually and recently been attained, and for this reason the firm formerly did not give up hand work. Only when it became thoroughly convinced that apparatus manufactured by means of special machines had become so developed that they would satisfy the high demands of the house as to quality, it was decided to introduce this method of manufacture, and the Berlin works arranged accordingly.

(To be continued.)

OPENING OF THE PERTH ELECTRICITY WORKS.

The formal opening of the Perth electricity undertaking took place on Saturday, June 1, when a large company was invited by the Corporation to witness the proceedings. The Town Council was strongly represented both by present and past members, and the guests included Sir Robert Pullar and Mr. John A. Dewar, M.P., the latter of whom, while acting as Lord Provost, took a lively interest in the Corporation electric lighting scheme at the time it was in its earlier stages. The company was photographed before the opening ceremony took place, and on this having been done Lord Provost Macgregor was presented with a gold key by Mr. W. C. C. Hawtayne, the consulting engineer for the work. After acknowledging Mr. Hawtayne's gift in a suitable manner, the Provost opened the gates and admitted the company into the engine-room. When a short time had been allowed for inspection of the engines, the Lord Provost turned on steam to one of the two 200-kw. sets, and Sir Robert Pullar turned on steam to the other set. This part of the opening ceremony having been gone through, the Provost requested Mrs. Wright, the wife of the convener of the Electric Lighting Committee, to switch on the light in the station, which that lady at once performed, amid cheers from the company. Mr. Callender here presented Mrs. Wright, on behalf of the contractors, with a handsome gold bracelet in a suitably-inscribed morocco case. Ex-Bailie Wright having thanked the contractors, Councillor Grieve, sub-convener of the Lighting Committee, switched on the light to the arc lamps in the streets of the town, and also to a number of private installations which are now connected up to the town supply. After a further inspection of the station, the company sat down to a cake and wine banquet, presided over by the Lord Provost, with ex-Bailies Wright and Mr. John Bigg, town clerk, acting as croupiers.

After the loyal toasts had been honoured, Bailie WOOD proposed the toast of "The Engineers and Contractors." In proposing this toast he paid a high tribute to Mr. Hawtayne for the manner in which he had performed his part of the undertaking, and also complimented the various contractors for the expeditious way in which they had carried out the work. The Council were fortunate, he said, in having Mr. Lambert appointed as resident engineer, and they looked to him to make the electric undertaking a great commercial success.

Mr. HAWTAYNE and Mr. CALLENDER having suitably replied,

Sir ROBERT PULLAR proposed "The Town Council." He was sure that the Town Council had been wisely expending the money of the ratepayers, as they had often done on previous undertakings, and he felt certain that the electric light would be a great pleasure and comfort to the citizens who adopted it.

Lord Provost MACGREGOR, replying on behalf of the Council, thanked them for the assistance they had always given to him. It was very arduous work, and growing more arduous every day.

Digitized by Google

Mr. DEWAR, in proposing "The Committee," referred to the amount of hard work which had been done by the gentlemen who were specially in charge of the electric lighting movement. He gave some interesting information regarding the amount of money spent by the city of Perth in the last 10 years or so. This amounted to about a quarter of a million of money in capital expenditure, most of which had been spent on productive work, and would yield a return to the community. He recalled the long period during which their principal effort as a Town Council was to keep others out. This "hold-the-fort" policy was pursued until ultimately they had to procure a provisional order and to proceed to lay down an electric lighting plant for themselves. He hoped the Corporation would soon have the tramways under their control, operated as an electrical system from the station now opened.

The toast of "The Committee" having been duly honoured, the LORD PROVOST, in the name of the Town Council and friends, presented ex-Baillie Wright, the convener, with a handsome silver salver, suitably inscribed, and a purse of sovereigns as a memento of the occasion.

Ex-Baillie WRIGHT replied on behalf of the committee, and thanked the subscribers for their gifts.

The toasts of "The Ladies" and "The Lord Provost" having been proposed and responded to, the proceedings terminated.

ELECTRICAL ENGINEERS (R.E.) VOLUNTEERS.

Official Opening of Headquarters.

Lord Kelvin, the honorary colonel Electrical Engineers (R.E.) Volunteers, presided last Saturday at the formal opening of the drill hall, which has been erected in Regency-street, Westminster, for the sole use of the corps.

Major R. S. ERSKINE, O.C.E.E. (R.E.) Vols, gave a brief sketch of the history of the corps, which emanated from a proposal by the late Dr. J. Hopkinson, in consequence of which the Institution of Electrical Engineers appointed a committee and invited applications. In 1897 Major Hopkinson began to form the corps, and the strength was 120 in 1898 with an efficiency of 115, which figures rose in the next year to 219 and 210 respectively, and in 1900, including the South African contingent, to 380 and 352. The present strength is 494, including the second South African contingent. The limit is 580. It was first proposed to instal the headquarters at Woolwich, and an office was taken at 13, Victoria-street. The 1st Middlesex Regiment greatly assisted with regard to drill and lent their headquarters, Sergeant-Major Stephenson inspecting the men. Assistance was also given by the London Scottish and Fusiliers, and Dr. Bateman, surgeon-captain London Irish Volunteers, gave his services in inspecting the applicants in town. The corps had now their own medical officer, and men would be inspected at headquarters. Owing to the great difficulty of working the corps from an office only, and to the difficulty of getting the said South African detachment together owing to objections by other tenants, it became necessary to look about for a building of their own. The estimated cost of the present building was £7,000; the War Department allowed a loan of £6,000 and also another of £1,000 to be borrowed privately. They would, however, not grant this loan of £6,000 until after completion of the building. A guarantee of the officers, backed by other guarantors, finally secured the capital required. Mr. Sydney Morse had acted as the corps legal adviser free of charge. Mr. Weyman was the architect of the building.

Captain E. Hopkinson, on behalf of himself and Mrs. J. Hopkinson, presented a large portrait of Dr. John Hopkinson. Subsequently Lord Kelvin asked Mrs. J. Hopkinson to formally declare the building open. Both Lord Kelvin and Colonel Crompton then referred feelingly to the eminent services of Dr. Hopkinson as the founder of the corps, and Colonel Crompton gave an account—and a most favourable one—of the doings of the said detachment in South Africa.

Major Erskine stated it was the intention of presenting Mrs. Hopkinson with a silver model of the searchlight, but the presentation had to be postponed, as the model was not quite ready yet.

The building consists of a very large and lofty hall, well lighted from above, spacious offices, and a number of recreation and lecture rooms. A small Morris tube is fitted up in the basement. The headquarters will be open every evening to members of the corps for instruction and recreation, and will no doubt be greatly conducive of quickly bringing the number up to the full establishment.

ELECTRIFICATION OF THE DISTRICT RAILWAY.

A special general meeting of the proprietors of the Metropolitan District Railway Company was held yesterday at the Westminster Palace Hotel for the purpose of considering additional provisions in the Bill promoted by the company for the conversion of their system to electric traction, and of adopting a provisional agreement between the railway company and the Metropolitan District Electric Traction Company, Limited. The object of the additional provisions and agreement is to render unnecessary those clauses of the Bill as deposited in Parliament by which powers were sought to raise new first debenture stock, to cancel certain authorised capital, and to reduce the dividend on the preference stock. From the remarks of Mr. Forbes, the chairman of the railway company, who presided over yesterday's meeting, we gather that the combination which has been formed, with Mr. Yerkes at its head, in order to carry out the electrification of the District Railway have taken up about half of the ordinary stock of the railway company, and are ready to find the money to provide the machinery for the conversion of the railway from steam to electric traction. The chairman impressed upon the meeting the fact that these gentlemen are quite willing to stake their fortunes and their reputations on this undertaking, and, what is more, they have given tangible security. The agreement between the railway company and the traction company has been the source of very great deliberation, and as it now stands it may be divided into two parts. First, with regard to the proposed generating station in Lots-road, Chelsea—this will be erected by the traction company at a cost not exceeding £400,000, and on completion will be hired to the railway company for 999 years at a rental based on 5 per cent. of the outlay per annum. With regard to this work, the chairman stated that it will be carried out, not under a lump sum contract with any particular firm, but by placing contracts with different firms best fitted to deal with the particular class of work in hand. This will ensure the work being done at the lowest possible cost, and the shareholders will have a voice in determining what the cost price shall be. With regard to the electrification and equipment of the railway for working by electric power, this part of the contract differs from that relating to the generating station. Under the agreement the work is to be carried out by the traction company, payment being made by the railway company in £500,000 ordinary stock and £166,000 4 per cent. debenture stock. The half a million of ordinary stock, the chairman explained, will be taken up by the American combination at the normal price of 25, and the 4 per cent. debenture stock at par. One point of particular interest is that the traction company assert that they will carry out the conversion of the system without interfering at all with the regularity of a single train in the ordinary service. The chairman's statement as to the proposals of the Board brought several shareholders on their legs. Some wanted to know what benefit they were going to derive from the conversion of the line to electric traction; others, why the Americans had elected to come over here and invest their money in the concern. Mr. Forbes's reply, that he supposed it was because the Americans had such a lot of money that they did not know what to do with it, was not generally accepted. He emphasised the fact that these American gentlemen had undertaken to do a thing which this company might very well have done for themselves years ago had they had the necessary knowledge and the necessary courage to carry out the scheme. This was a very momentous and important question, and he deplored the

Digitized by Google

fact the attendance of shareholders that day was so limited. Mr. Perks, M.P. (whose name has been associated with that of Mr. Yerkes in certain quarters in connection with this undertaking), took this opportunity of stating that he has not got one single pennyworth of interest, either professionally or otherwise, in the new company which will undertake the electrification of the railway. He is practically the largest holder of ordinary stock in the railway company, and his advice to the Board has always been given in the nature of a friend and not in the capacity of a professional man. Another important point which transpired during the discussion is that until one million sterling has been raised by the new company the agreement is not binding on either party. It was further stated that the new company will make no profit whatever on the carrying out of the work. This syndicate of American gentlemen, who, it is asserted, are of undoubted position and means, look to the future for their real remuneration. The necessity for carrying the Bill through this session of Parliament was impressed upon the meeting, it being pointed out that already a Bill was before Parliament for the construction of a "tube" railway along Fleet-street and the Strand, which, if authorised, will very seriously compete with the District Railway. Other shareholders expressed the hope that the relations between this company and the Metropolitan Company will continue to be of an amicable nature, while others wanted to know what were the practical advantages of electrical traction over steam. The chairman agreed that they ought not to take up a position of opposition to the Metropolitan Company, but if the latter company adopted a system of electric traction which was fatal to the District Company's views, then they would have to take the same course as with other companies and protect themselves. Although he earnestly hoped that their relations with the Metropolitan Company would continue friendly, he might say that there was no chance at present, as had been suggested in some quarters, of an amalgamation between the two companies. Referring to the agreement, the chairman stated that the Board were unanimously of opinion that it was perfectly sound, and was fraught with enormous advantages to the shareholders in the railway company. He appealed to them not to imperil the progress of the scheme in Parliament, and in their own interest to allow the Bill to go upon the terms stated. With regard to the practical advantages of electricity as the motive power, in the first place the company could run more trains a day at a much less average cost per mile than by steam. At the present time they were spending 52 per cent. on the working expenses, whereas with electric traction they were assured that the lines could be worked for 35 per cent., which would mean a saving of £70,000 to the company per annum. Ultimately the resolutions for the promotion of the Bill in this session of Parliament and the adoption of the agreement with the Metropolitan District Electric Traction Company, Limited, were unanimously agreed to.

MUNICIPAL ELECTRICAL ASSOCIATION.

We have seen the official programme of the annual meeting of this association, which is to be held in Glasgow on June 19 and the three following days. It is probably generally known that visitors are cordially welcomed to the meetings of this association, the necessary tickets being obtainable from the secretary, Mr. C. McArthur Butler, at St. James's Hall, London, W., up to the 12th inst.; after that date the secretary will be found at the Windsor Hotel, Glasgow.

The programme, as usual, is a lengthy one. It will, however, be only necessary for us to indicate the business, leaving such readers as desire it to obtain the programme from the secretary and make themselves acquainted with the details. On Wednesday, the 19th, the business of the meeting commences at 9.45, at the Institution of Engineers and Shipbuilders in Scotland, when the Lord Provost will welcome the association, and the president, Mr. W. A. Chamen, will read the presidential address, subsequent to which the following papers will be read and discussed: (1) "Insulated Returns in a Tramway System," by Mr. J. H. Rider, chief electrical engineer, London County Council tramways; (2) "Street Electric Lighting," by Baillie W. Maclay, convener of the Glasgow Corporation Electricity Committee. The meeting for reading and discussion of papers will be adjourned at half-past one, and after luncheon various works will be visited prior to the annual dinner, which will be held on that evening.

On the following day the meeting commences at 10 o'clock at the Freemasons' Hall, Edinburgh, when the following papers will be read and discussed: (1) "Braking Apparatus for Electric Cars," by Mr. A. L. C. Fell, tramway engineer to the Sheffield Corporation; (2) "The Equitable Allocation of Costs in Combined Lighting and Traction Stations," by Mr. W. H. Tittensor, electrical engineer, Dundee Corporation. After the reading of the papers visits will be made to places of professional interest in and around Edinburgh.

On Friday the meeting takes place at the Institution of Engineers and Shipbuilders'. The following are the papers to be read and discussed: (1) "Refuse Destructors in Combination with Electric Power Stations," by Mr. J. S. Highfield, electrical engineer, St. Helens Corporation; (2) "Coal and Ash Conveying Gear," by Mr. R. A. Chattock, chief electrical engineer, Bradford Corporation.

As usual, a number of works are open for inspection. In the evening the annual general business meeting will be held. Saturday is to be devoted more or less to a visit to the works of Messrs. Babcock and Wilcox.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following is the report of the committee of the Students' Section for the session 1900-01:

During this session 11 ordinary meetings have been held, the average attendance at which has been 20. At some of these meetings have been read some of the reports presented to the Institution by the student reporters appointed by the Council of the Institution, in August last, to report on various classes of exhibits in the electrical section of the Paris Exhibition of 1900. In addition, six papers have been read on various electrical subjects.

Thirteen works and installations of special interest in the neighbourhood of London have been visited by parties of students during the session. Eight visits have also been made by parties of student members from the various technical colleges to the Board of Trade standardising laboratory, at the invitation of Mr. A. P. Trotter, of the Board of Trade.

It is with great pleasure that the committee reports the success of the visit of the Students' Section to Manchester in April last.

The proposal to visit an engineering centre in the Easter vacation of the technical colleges was brought forward in December last, and, with the approval of the Council, a circular letter was sent to all the student members in order to test whether the proposal would meet with sufficient support. To this circular 33 replies were received, and it was considered that this was a sufficient number to warrant arrangements being made for the visit to take place. Manchester was chosen as the centre for the visit, which lasted four days (one day being spent at Liverpool), and was participated in by 32 students, 11 of whom were from London, the majority of the remainder being from the neighbourhoods of Manchester and Sheffield. The party was well received by the firms and engineers whose works were visited, and the success of the visit leads the committee to hope that the experiment may be repeated in future years.

The committee have during the session drawn up a code of rules for the governance of the Students' Section, which was unanimously passed, subject to the approval of the Council at the annual general meeting of the section.

The committee for the session 1901-02 is made up of the following gentlemen: B. H. Morphy and C. W. Wilkinson (Central Technical College); A. H. Bennett (Faraday House); R. L. Longman, P. G. Mitchell, and P. Rayner-Smith (Finsbury Technical College); D. R. H. Browne (King's College); F. J. Hiss, jun., and H. D. Symons (non-collegiate); G. B. Dyke (University College).

Book Received.—The first edition of a new work entitled "A Treatise on Electromagnetic Phenomena," by Commander T. A. Lyons, of the U.S. Navy, has just been published by Messrs. Chapman and Hall, Limited, of London. The price of the book is 25s. 6d.

ELECTRICITY AND MUNICIPAL TRADING.

This is the title of a communication to the *Times* on Saturday, June 1, to the extent of between four and five of its columns, and upon which communication our contemporary founded a leader. We propose to follow so eminent an example. In the first place, we are strenuously opposed to all that partakes of municipal trading, yet our present purpose is to show that its exponents have much to say in favour of the present condition of things. In our opinion, its opponents are hardly fair in the controversy. So far as we can find, with the exception of ourselves, there has been no attempt to obtain or define a principle in the matter; the whole controversy takes the form of special pleading, and each side argues as if the opposite side were unworthy of consideration. The correspondent of the *Times* chooses his subject "for the reason that probably the present tendency of corporations to seek to compete with private enterprise owes its growth to nothing so much as to the introduction of electricity as a source of light and of traction and motive power." A quarter of a century's experience with corporation work has led us to the conclusion that the prevailing idea in the minds of corporation officials and councils at the time when it was proposed to introduce electrical energy for lighting purposes, was that under no circumstances would it be beneficial to the community at large to promote the introduction of a monopoly similar to the monopoly exercised by the gas companies. At that time gas had held the field for more than half a century. The gas companies had done little or nothing to improve the gas supply or burners; and, in fact, the great progress made in the gas industry has been almost entirely due to the introduction of the competing factor—electrical energy. A great many gas companies were paying, and had paid, large dividends, and it was generally felt throughout the kingdom that too much profit was being made by these monopolists out of the necessities of the population. It is all very well for the advocates for the development of electrical work to pretend that it is not going to follow in the footsteps of gas, and become more or less of the nature of a monopoly in each district. It must in the long run partake very much, if not wholly, of the nature of a monopoly in each district. What is the use of pretending that it will be otherwise, and in attempting to fool the general public into the belief of the impossible? What, again, is the use of arguing as if the street area was illimitable? It is not; and if there were no other reason, this would be sufficient to quash any idea of general competition. We will take the liberty of mentioning another point to show the one-sidedness of the argument put forward. It is stated, and no doubt it is perfectly true, that "there are over two hundred local authorities in the British Isles at the present moment holding provisional orders which have never been put into force." We wonder how many companies during the last twenty years have projected electrical schemes and obtained capital from the public without their schemes being put into force. It is

Digitized by Google

the company promoter who has compelled, in a large number of cases, the local authorities to take measures for self-protection. These promoters care nothing about the real introduction of electric light or anything else, except to be able to make much money out of promoting schemes. We are not going to enter again at this time upon the vexed questions of traction and motive power. We have often stated our belief that these are absolutely outside the true work of municipal authorities. Rather let us indicate one or two points which the opponents to municipal trading might expand with advantage to themselves. Is it not a fact that anything of the nature of a monopoly is a bar to anything in the shape of progress in the direction of that monopoly? It seems to us that the march of time has, even with electrical matters, solved that question. We are told that the future of electrical generation is to be upon an enormous scale, and that the time of a comparatively small station is short. If this is to be so, what greater object lesson could the country require. Scores, or hundreds, of these small stations have been installed during the past fifteen years, and if the success of the large generating station is commensurate with the ideas of their advocates, it will be seen that it is far too dangerous for public money to be put into concerns which are characterised by rapid changes.

ELECTRIC LIGHT UNDERTAKERS AND THE NEW FACTORY ACT.

The Bill of Mr. Ritchie to add certain definitions to the Factory Act of 1895, which is an amendment of the Consolidated Factory Act of 1878, has definitely included *electrical generating* and *transforming* stations in the "premises" which are to be inspected by the factory inspectors under the Home Office. If electricity was not an article of manufacture and sale, generating stations could not be included; and if transforming stations were not—in the terms of the Act of 1878—"attendant" on the manufacture of electricity, this could not have been proposed. Any attempt to have the question discussed on independent grounds is precluded by the influence of the Workmen's Compensation Act, from the benefits of which electric light employés might be excluded if the premises in which generation and transformation takes place were not subject to the Factory Acts. If this is the case, any attempt to leave these places out of the definitions in Mr. Ritchie's Bill would meet with opposition, certain to be successful. We understand that street boxes are not "premises," so that they would not be included amongst the various kinds of transforming stations to become subject to the Factory Acts. As there is apparently no chance of being able to show that an electrical generating station for the production of electricity that is for sale is *not* a non-textile factory, the next thing is to try and bring the requirements of the factory inspectors under the influence of professional opinion, so as to prevent, for instance, machinery in a supply station under statute being put out of use under the decision of a magistrate on the motion of an inspector. We believe that the Council of the Institution of Electrical Engineers has this question, so important to prevent unnecessary hampering of the industry, under careful consideration, and that they will seek to obtain a hearing on it, and to maintain a watch in the future on the incidence of this new legislation.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BRIGHTON CABLES.

SIR,—I am not interested in the discussion which has taken place in the columns of the *Electrical Engineer* as to the relative tenders submitted by the firms comprising the Cable Makers' Association and the Union Cable Company, excepting on the point raised in the letter from the latter company published in your last issue. An attempt is therein made to explain away the discrepancy in prices by the Union Company taking credit for supplying cables having an electrical conductivity 4·68 per cent. in excess of the cables supplied by the Cable Makers' Association.

To my mind the apparent conductivity inferiority will be found to be due to the adoption of a different temperature basis; the guaranteed resistance in the unsuccessful tenders was most probably based on a standard temperature of 75deg F. If this is so, then there is practically no difference in the respective guarantees of the Cable Makers' Association and the Union Cable Company. But whether this be so or not, there is certainly not a difference of 4·68 per cent. in the conductivity of the copper used by the contending parties.

The high-conductivity copper supplied by my firm is always over 100 per cent. on Matthiessen's standard, and averages nearer 101 per cent. The high-conductivity copper used by the Union Cable Company is, therefore, claimed to be 104·68 to 105·68 on same standard. Where do they get it from? It certainly is not made on a commercial scale neither in this country nor in America.—Yours, etc.,

W. GIBBINGS,
Works Manager to the Liverpool Silver and Copper Company, Widnes.

PERPETUAL MOTION.

SIR,—I beg to own receipt of your favour of 29th inst., and to say emphatically I have entirely overcome the laws of gravity (you say nature) by utilising the whole weight of the wheel to drive itself by a scientific arrangement of levers and driving weights, and that my invention will rank among the most wonderful achievements man is capable of fathoming, and will shortly take the world by utter amazement. Candidly, Sir, yourself, or anybody else, could have no conception as to how it is done, and why you should be so stubborn, and disbelieve what I say, and adhere to the laws of gravity when my invention will knock the shine out of any other since the world was made, I fail to localise, unless it is your policy to harness the inventive propensity of man. If you could pay me a visit, Sir, I can show you something to go back and write upon for the enlightenment of those puzzling their brains over perpetual motion, resulting in the making of your journal. Don't be stagnant! Be enterprising, like our shrewd American cousins.—Yours, etc., ARTHUR E. GILBERT.

Heaton, May 31, 1901.

[The above letter from Mr. Arthur E. Gilbert is the outcome of one we wrote him respecting an invention of his, which he claims is to be the invention of the new century. We regret to find that he is still wasting his time, and, we presume, his money, on the vain attempt to produce a perpetual-motion machine. We have again and again tried to convince Mr. Gilbert that he would find instruction in theoretical mechanics of great use to him, without being able to do so. As regards the proposed visit, we are quite prepared to arrange for one of our editors to

Digitized by Google

call upon him at Heaton as soon as he can inform us that he has had the machine running for a day without the application of any external power.—ED. *E. E.*]

CUT-OFF DEVICE.

SIR,—We thank you for the copy of the above paper issued on the 31st ult., and also for the insertion you have respecting our "cut-off" device. We beg, however, to ask you to correct in your next issue the wording of that description, as it is somewhat misleading, and might prove very prejudicial to our interests. You state "that each span shall be independent of its neighbours." Now, this is not so, as we guarantee that our appliance shall be effective in cutting-off the electric current to the extent of six spans, which means, of course, a distance of 240 yards.

Further, with regard to "adding to the somewhat unsightliness of tramway construction," we also beg to state that the device itself when fixed on the pole and painted in harmony with its surroundings is hardly recognisable from the ground, as the levers you mention in your description can be now dispensed with by a chain and a box containing the weights fixed on the pole.

In case of span wires, these would be sufficiently strengthened to carry the weight of the device, but still the chain and weight would be utilised in place of the arms and levers—in fact, our apparatus can be fixed anywhere.

We trust you will be able to give these corrections as prominent a place in your next issue as you did the description on the 31st ult.—Yours, etc,

BOSTOCK AND CHEETHAM.

Brighouse, Yorks, June 4, 1901.

OBITUARY.

We much regret to have to record the demise of Principal John A. Viriamu Jones, professor of physics in the University College of South Wales, in his forty-fifth year. Born at Pentreporth, near Swansea, in 1856, Prof. Jones matriculated at the London University in 1872, being placed first in the honours division. Having entered University College, London, he graduated bachelor of science in 1875, carrying off the university scholarship in geology. Prof. Jones next went to Balliol College, Oxford, where he won a Brackenbury scholarship, obtained a first class in mathematical honours in moderations three years later, a first class in the final honour school of mathematics in 1879, and a first class in the final honour school of natural science (physics) in 1880. In this year he accepted the appointment of demonstrator in the Clarendon Laboratory, Oxford, under Prof. Clifton, and a year later he was appointed principal and professor of mathematics and physics in the Firth College, Sheffield. Prof. Viriamu Jones had occupied this high position for only two years when he was elected principal and professor of physics of the then newly-founded University College of South Wales, a post which he has ably occupied for the last 18 years. The scientific work of Prof. Jones was mainly concerned with the absolute measurement of electrical resistance, and he was a member of the British Association on that subject. In 1894 he was made a Fellow of the Royal Society, and three years later was elected a Fellow of Jesus College, Oxford. As principal of the South Wales College, he did much for the cause of technical and scientific education in Wales. A memorial service will be held in Cardiff on Monday next, and the remains of the deceased scientist will be interred at Swansea on the following day.

THE MOND GAS BILL.

The object of the Mond Gas Bill is to incorporate and confer powers on the South Staffordshire Mond Gas Power and Heating Company to supply a producer gas invented by Dr. Ludwig Mond. The main features of the invention were explained before the Select Committee of the House of Commons presided over by Colonel Welby, which has been enquiring into the merits of the Bill. The gas is purely a power and heating gas, and cannot be used for lighting purposes, its flame being similar to that obtained from spirits of wine. It can be produced from cheap slack, and as the sulphate of ammonia is recovered in the process as a by-product, the cost of the coal, and consequently of the gas, it is claimed, is reduced to a very small figure. The present application to Parliament was practically only to obtain powers to open up streets in order to lay mains for distribution purposes. One of the great advantages which it is claimed will result from the establishment of the company is that they will be able to supply power and heat to the small manufacturer at a very low rate—more cheaply, it is said, than electricity for these purposes can be supplied. Mr. Herbert Humphrey is responsible for the engineering features of the scheme, and, in his opinion, the use of Mond gas will lead to a saving in fuel, in labour, in time, in cost of repairs, and in space, and will give better results with less waste of material than ordinary fuel. The estimated expenditure of the company is £789,686, of which £40,000 is for land, railway sidings, etc., and £387,000 for works at the manufacturing stations, making a total of £427,000, which leaves £360,000 for distribution plant. Altogether it is proposed to erect five manufacturing stations, from each of which will run a 2ft. 6in. arterial main in each direction, which it is estimated will be capable of delivering 120,000,000 cubic feet of Mond gas daily. A considerable number of local authorities opposed the measure, chiefly on the ground of the interference with the streets which the operations of the company will entail. In other cases the ground of opposition was because they supplied coal-gas, with which it was feared the new gas might compete. In answer to this, however, the promoters pointed out that it would only compete where gas was supplied for power or heat, and then only in the larger quantities, because it would not pay to undertake to supply the very small consumers with Mond gas for these purposes. Among the petitioners was the Midland Electric Corporation for Power Distribution, who have power to supply electrical energy in a certain portion of the area proposed under this Bill. The answer to their petition was that an electrical company could supply energy for power, but not for heat. There was also opposition on behalf of six gas companies in the district.

One point put forward by the petitioners was that although the promoters sought power to supply Mond gas, they might not, under this Bill, supply Mond gas at all, but some other producer gas, and accordingly the promoters agreed to the insertion of clauses making it clear that that was not their intention. A question also arose as to whether the undertaking would prove a financial success. It was stated that the company could only start when £225,000 had been subscribed, and Dr. Mond's remuneration, which was to be £75,000 in ordinary shares, entirely depended upon the success of the undertaking. The following provisoes were also inserted on the suggestion of the committee—viz: Any development of the gas permitted by the Bill must be certificated by the Board of Trade. The shares to be allotted to Dr. Mond, the patentee, to rank as follows: 40,000 to rank for dividend with the other shares, 35,000 to rank for dividend after the holders of the other shares have received 5 per cent. per annum dividend. Subject to these conditions the committee found the preamble of the Bill proved.

LIGHT RAILWAYS.

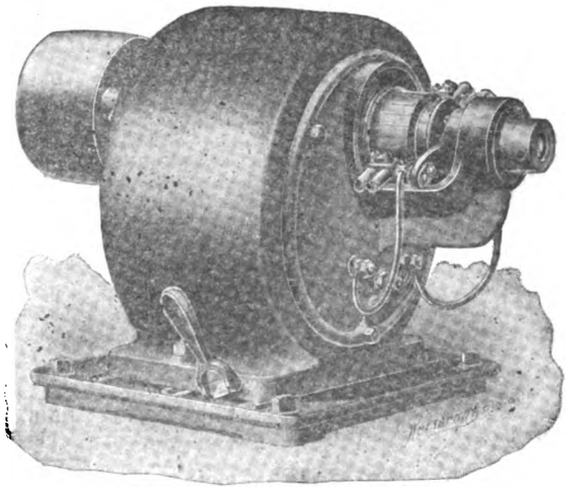
Notices of intention to apply for light railway orders have been given by the following: Lizard light railway (company), electrical power, etc.; Woodbridge and Bawdsley light railway (syndicate), construction of two lines; Gower light railway (company), amending order; Rother Valley light railway (company), construction of three lines; Turton, Tottington, Ramsbottom, and Rawtenstall light railway (company), construction of six lines; Spen Valley and Morley light railways (British Electric Traction Company), extensions; Crewe light railways (British Electric Traction Company), eight lines; South Shields,

Digitized by Google

Sunderland, and District light railways (British Electric Traction Company), construction of five lines; Potteries light railway (Potteries Electric Traction Company), extensions; Middleton light railways (British Electric Traction Company), deviation; Southend, Burnham-on-Crouch, to Bradwell-on-Sea light railway (Railway and General Construction and Maintenance Company), construction of five lines; Woolwich, Eltham, and District light railways (the Auxiliary and Light Railways and Tramways Company), construction of one line; Preston-Horwich light railways (the Auxiliary and Light Railways and Tramways Company), construction of five lines; Preston and Lytham light railways (syndicate), construction of four lines; Holmfield and Southowram light railways (syndicate), construction of two lines; Southowram and Elland light railway (syndicate), construction of six lines; Crowland and District light railways (company), extension of time.

THE STERLING DIRECT-CURRENT MOTOR.

The Improved Electric Glow Lamp Company have taken up the manufacture of motors on lines which, commercially, must be acknowledged to be correct lines. Thus the company are making only two sizes of frames, and these will be reproduced in great quantities. The frames being stocked, and also standard windings for the same, the firm will be able to give very prompt delivery. The winding will be varied to suit standard voltages and speeds, and made so interchangeable that at a small cost the voltage of the motor can be altered to suit changes in standard pressure of supply. The sizes of frames chosen are such that one gives ½ h.p. at the rather slow speed of 1,200 revolutions per minute, and the other ¼ h.p. at 1,000 revolutions per minute, and with a very high efficiency and large overload capacity. These speeds are well suited for direct belting to ordinary line shafts and many types of machines without the use of countershafts, gears, or other speed-reducing devices.



The illustration shows the general appearance of these motors. Another good feature in the list before us of the Sterling motors is that the prices include automatic release starting switches.

BLACKBURN ELECTRICITY WORKS.

The accounts of the Blackburn Corporation electricity department show a total expenditure on capital account to March 25 last of £117,724. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are given herewith:

Dr.	Revenue Account.	£	s.	d.
Coke, coal, etc.		4 326	7	5
Oil, waste, water, and stores		372	7	11
Wages at generating station		1,283	14	6
Repairs and maintenance of buildings		34	14	4

ST. PANCRAS ELECTRICITY ACCOUNTS.

The following is the report of Mr. Albert E Pycraft, chief clerk to the St. Pancras Borough Council, on the working of the electric lighting department during the past year. Abstracts of the revenue account, general balance sheet, and statement of electricity generated, sold, etc., are also appended:

During the year a loan of £24,320 has been received, making the total amount received at Dec. 31, 1900, by loans of £261,100. Of this amount a sum of £21,186. 14s. 3d. has been repaid. A loan of £77,111 in respect of capital expenditure to the end of

Digitized by Google

1899 was applied for to the London County Council in June last, but up to the present has not been received. The expenditure incurred during the year on account of capital amounts to £50,248. 2s. 1d., making a total capital expenditure of £336,794. 14s. 1d. The gross revenue for the year amounts to £49 329. 10s. 2d., an increase over the year 1899 of £4,449. 3s. 2d. This is accounted for by an increase of £3,207. 7s. 8d. received for public street lighting in consequence of an additional 198 public arc lamps having been erected during the year (equal to an increase of 87 per cent.), and £1,241. 15s. 6d. on account of private lighting, etc. The small increase from private consumers is due chiefly to the reductions made in the charges for supply since June, 1900. The total units sold during the first half of the year was 1 056 613, and realised per unit sold 4 48d., and for the second half 1,239,773 units, equal to 3 63d , the difference in price representing a money value of £4,390. 17s. 3d. The result of the year's trading is accounted for by several special circumstances: (1) The reductions in the charges for supply as above (2) The increased price for coal. The average increase in the price of coal over the year was 3s. 3d. per ton, the total consumption being 12,026 tons, representing a money value of £1,954. 4s. 6d. (3) Exceptional charges in connection with alterations carried out at Regent's Park Station, amounting to £944. 19s. 3d. The following table shows the progress of the electricity undertaking since the commencement:

Year ending Dec.	No. of consumers.	Current sold to consumers (not including public street lighting). 3d. per unit. £ s. d.	Current sold to consumers (not including public street lighting). 4d., 5d., and 6d. per unit. £ s. d.	No. of lamps etc., applied for. Incandescent. 16c.p.	No. of lamps etc., applied for. Arc.	No. of lamps etc., applied for. Motors.
1892	172	—	8,167 7 8	9,990	82	11

CATALOGUES RECEIVED.

Messrs. Mavor and Coulson, in issuing a new list of the various machines manufactured in their electrical shops, commence the same by instructing their customers how to ask for an estimate. We can quite believe that there is a great necessity for this, and that large firms like the above have to waste a great deal of time and money in preparing estimates which are based on assumptions as to local conditions. It is always much more satisfactory if the would-be customer would give a sufficient description of what the electrical plant has to do to enable firms to give a reliable and close estimate. In this catalogue we find descriptions and lists of a great variety of direct-current plant suitable both for belt driving or for direct coupling. As the firm are doing much work in electric motors for workshop distribution, or for use in collieries, we are not surprised to see in the catalogues a description of a number of electrically-driven accessories. The list is completed by a description in full detail of the Mavor and Coulson C.C. system of concentric wiring.

We have received from Messrs. Mather and Platt, Limited, who have their works in Machester and their London office at 14, Victoria-street, Westminster, a copy of the fourth edition of their catalogue. Besides containing a list of the plant manufactured by this pioneering firm, there is also included in the little volume some useful tabular matter such as is often required by an electrical engineer when working out schemes. The lists of dynamos and motors which are given are most complete, and, in addition to the prices, information as to the space occupied and the weights of the parts are added. Not the least useful portion of this pocket catalogue are those devoted to the electrically-driven specialities manufactured by the firm.

The Berliner Telephone Manufacturing Company, whose agency in this country is worked from 117, Queen Victoria-street, have forwarded to us a copy of their last list of telephones and telephone accessories. A recapitulation of the numerous articles connected with telephone exchanges which are included in this list, would lose interest on account of its great length. The completeness, however, of the list, might be summed up in a few words, by saying that everything required for telephoning is included, except the lady operator.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

383. I have charge of an installation comprising gas-engine and shunt dynamo of about 8 kw., voltage 100. There is also a battery of 53 cells. I wish to charge up 20 new cells. What is the best means of obtaining a steady current at reduced voltage?—A. R.

384. How would you start the design and the general design of a 1,000-watt four-pole dynamo with slotted armature, 1,000 revolutions, 100-150 volts? I know the general workings, such as construction of commutator, armature, bearings, etc., also a knowledge of the magnet and electrical calculations, but have had no experience in the designing of electrical machinery.—W. H. H.

ANSWERS.

Question No. 377.—The supply from a large station fails suddenly near the maximum load through the breakdown of an armature. The output at moment of failure is 2,000 kw. from a number of shunt-wound direct-current machines in parallel. How would you restart the supply so as to restore normal pressure in quickest possible time?

Answer to No. 377 (*awarded 7s. 6d.*).—The best way to start up after a total failure such as that described in the question will depend largely on the way the machines are excited. There are three common modes of arranging the exciting circuits for direct-current generators: (1) the shunts of all dynamos connected to the lighting 'bus bars; (2) shunts connected to a battery; (3) shunts supplied from a special engine and dynamo.

All three methods have certain disadvantages. Methods (2) and (3) are objectionable by reason of the fact that the interruption of the circuit supplying the exciting bar breaks the exciting circuit of all the generators. Of the two methods, excitation from a battery is to be preferred, as less liable to interruption if the battery is used for that only; but the cells should be lead lined in wooden cases to avoid risk of a glass cell breaking. Method (1), which was the method almost universally used in the early days of the supply industry, is open to several serious objections which seem to be contemplated by the question.

Inasmuch as the failure described would hardly have occurred had either of the two last methods of excitation been in use, we shall assume that the fields of all the dynamos are excited from the 'bus bars, which, of course, are always maintained at the proper pressure. In this case the result of a serious short is to more or less demagnetise all the machines by reducing the resistance of the external circuit to a very low amount. The action is further aided by the fact that a large demand is made for current from the machines that are running, which tends to make the output of current from each machine greater than its critical value. If this is exceeded, the drop in volts is so great that the excitation is rapidly diminished, and the two actions react on one another, until in a few seconds the dynamos may be running round without generating any power. They have lost their fields. In such circumstances the first thing to be done is to make the machines excite, and to do this it is necessary that the external resistance should be increased. The generators must be switched off, and run at full speed until they do excite and give normal voltage. If they could be *all* switched in at exactly the same moment fully excited, it is possible that the supply might be restored, but as this cannot be done practically, we must increase the external resistance till it is of such a value that one of the dynamos can safely give the current demanded. This can be done by disconnecting the near feeders, leaving, perhaps, only one of the furthest connected. The dynamo is now switched in, and the other machines switched in parallel as quickly as possible, more feeders being switched on as the dynamos are put in parallel, until all the machines will be taking their normal load.

Should any method of separate excitation be in use, when the failure occurs great care must be taken that no dynamo is switched on until the short has been removed. Assuming there has been a failure, it will not be safe to switch a 500-kw. machine on to a load that was previously taken by, perhaps, five similar machines in parallel, so that some of the load should be thrown off as above described before the generator is switched in. In the case of separate excitation, however, we might proceed in another way. If it were possible to vary the exciting volts from normal down to a very small value, the machines should be run at proper speed (all of them), with armature switches closed and the exciting circuit volts gradually built up, when all the machines would increase their output in about the same proportion, so that no machine would be called upon to carry an excessive load. If the exciting circuit voltage cannot be varied, the plan of running up all the machines simultaneously might be tried, the fields being fully excited, but it would be much more difficult to keep the different units properly loaded in this case. By the methods detailed above it should be possible to restore normal pressure in less than 10 minutes, though it is quite probable that it would take 20 minutes or more. The fact that the works are in darkness in such cases does not add to the ease or celerity of righting matters.—E. D. W.

Answer to No. 377 (*awarded 7s. 6d.*).—The failure of the supply due to the breakdown of an armature might be brought about either by the operation of the "minimum" cut-outs on the remaining machines—*e.g.*, the well-known incident at Brighton a good while ago—or else by the working of the "maximum" cut-outs of the same machines, according to which kind of safety devices they are fitted with, and depending also on the characteristic curves of these machines. If there be a battery connected to the 'bus bars, it should be provided with a "maximum" cut-out, or else it would be probably ruined by the excessive current it would be called upon to supply. Well, the first thing to do is to get some light on the subject: this may be quickly done by switching the station lights on to the battery; if there be no battery a couple of oil hand lamps should be always kept in a certain place where they are easily found, and should be ready for use at a moment's notice. In some stations a small machine is kept running of the stoker-gear shafting, and is of sufficient capacity to keep the works' lights going. Throw-over switches would have to be operated in this case also. It would be very bad policy to switch in a single machine on to the load, as one of two things would happen: either the armature might be burnt out (as was the case at Aberdeen a short time ago), as well as the engine being severely strained by the sudden rush of current, or else the dynamo, being shunt wound, would lose its excitation on being so much overloaded, both cases depending upon the capacity and the characteristic curve of the machine. The best thing to do, therefore, would be to simultaneously parallel two or more of the larger sets of the running plant; to this end they should be got to approximately equal voltages, and the switchboard attendant should have an assistant on the board to switch in simultaneously. It would be advisable to parallel them at a rather low voltage, so as to reduce as far as possible the inevitable strain on the engines when put on the 'bus bars. These machines would be able to carry the load at a somewhat reduced voltage while an additional set is being paralleled, and having got all the original plant running again except the broken-down set, the "stand-by" for the evening (the engine having been previously warmed up) should be run up to replace the disabled machine, which would have been shut down in the meantime. Of course, the rapidity of these operations would depend upon the presence of mind and resource of the shift engineer, whose mind should be fairly well trained as to what to do in the event of a general breakdown; as a

Digitized by Google

rule, however, a cut-and-dried scheme flies to the winds when a "bust" is in progress, and very often the engineer simply does the first thing that occurs to him.—D. J.

Answer to No. 377 *(awarded* 5*s.).*—It is not quite clear from the question how the armature of one machine failing should completely stop the supply, for in nearly all present-day stations the machines are in circuit with a maximum or minimum cut-out or fuses, or both, so that when the machine broke down the minimum would open, and the other machines would take up the load. If, however, the machine which broke down was a much larger set than the others, the over-load might be too great for them, and would open their maximum cut-outs or blow the fuses. From this it will be seen that it is no good to close the switches of the machines in the ordinary way when they are at correct voltage. I think the only safe way to start up is to get each engine on the stop valve running at a speed so that it will give about 10 volts; if the supply is at 440 volts, and the load 2,000 kw., the resistance of the load would be ·096 ohm; therefore, when the switch was closed, 104·2 amperes would be flowing. It can then be run up till it is nearly taking its full current; the other machines can then be paralleled with it (of course, at the lower voltage). When sufficient machines are in, the voltage will be correct; each machine as it is paralleled in raises the voltage a little.

It must be remembered that the load coming off so suddenly will cause a good deal of difficulty in the boiler-house through the steam blowing off, so that it would be advisable to let each machine run full speed till you are ready to put it in, when it will have to be slowed down to get the low voltage. If the machines are excited off the 'bus bars, all the shunt wires are connected to one of the horizontal bars, in which case the machines and feeders must be plugged on to that bar, and the machines will then excite themselves. If a battery is in use, it may be used to excite the machines by plugging it on to the bar to which the shunt wires are connected, provided that this bar is not feeding the town, as the battery must on no account be put on to the town till the normal voltage has been restored. If a motor balancer is used, it will be unnecessary to start it until the correct voltage has been reached on either of the sides.—C. L. E. S.

Question No. 378.—What is the best metal to make fuses of, and what is the best form for them to take on a main 500-volt switchboard carrying large currents?

Best Answer to No. 378 *(awarded* 10*s.).*—Fuses operate when the current is largely in excess of the normal, and in case of a short-circuit have to break a high E.M.F. Every fuse must be capable of breaking a "dead short" quickly, and without damage to contacts, etc., hence some effective means of suppressing the vicious and destructive arc often formed is imperatively necessary. Now, the gap bridged by the fuse is filled at the moment of breaking circuit with metallic vapour, and the most successful fuse, generally speaking, will be one which gets rid of this metallic vapour most quickly and effectively. It is also essential that a fuse should go *quickly* on a short-circuit. Experiments to ascertain what metal gives the quickest break have not, as far as the writer is aware, been made, but he has found that with a 230-volt short through four fuses, two of No. 22 copper (fusing current 60 amperes), and two of No. 14 tin (fusing current 37 amperes), the copper fuses are *always* blown, while the tin fuses sometimes go and sometimes do not. In another test, with one fuse No. 24 tin (fusing current five amperes), one two strands of No. 30 copper and two fuses of 22 copper, *all* the fuses were blown, apparently simultaneously.

Now, other conditions being equal, the metal which is least bulky should produce the smallest amount of vapour, and the metal which is the best conductor should break a given current quicker than a worse conductor, as the former may be so much smaller, and have, therefore, less radiating surface. Now, of the commoner metals the only one fulfilling both these conditions is copper, and in practice copper has been found to be by far the most satisfactory all-round metal for fuses.

Up to 300 or 400 amperes a number of copper wires in parallel will be quite reliable. For currents greater than this the use of magnetic cut-outs is to be preferred. If these are used one on each pole, preferably some distance apart, they form a very reliable and safe arrangement, as should a short not be cleared, on restoring the circuit the cut-out first set will break the circuit as soon as the other is reset. The most successful methods of suppressing the arc formed on breaking large currents at 500 volts pressure are: (1) using metals whose vapour will not sustain an arc; (2) interposing large masses of refractory material in and about the path of the arc to cool it; (3) arranging bridges of insulating and refractory material between the poles; (4) placing the fuse in a magnetic field which blows out the arc formed; (5) blowing out the arc by a current of air; (6) quenching the arc by covering the contacts with insulating oil of high flash-point at the instant of breaking. Probably (4) is the most satisfactory arrangement for continuous currents under the conditions laid down in the question.

It is often necessary to rig up a fuse from materials to be found in every station, and in such case a very satisfactory fuse can be made by clamping a strip of tin or copper sheet to two copper blocks about 4in. to 6in apart, and placing a good thick slate bridge between them. The bridge must protrude above the highest portion of the terminals (generally the bolt heads) at least 2in., and the strip is led *over* the bridge. Copper clamping pieces are used between the strip and the bolt heads to ensure good contact all over.—E. M.

Answer to No. 378 *(awarded* 5*s.).*—A copper wire makes the best fuse for large currents—in fact, all fuses for above 10 amperes ought to be copper; if copper is employed for currents below this, the wire is so slight that it is liable to get stretched or cut by the binding screw. Tin or lead should be used for smaller currents, as it has a larger

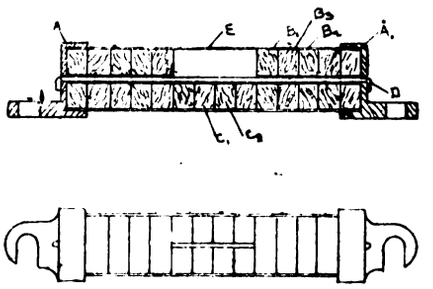

FIG. 1.

section than copper for the same current, thus not being so liable to get damaged. In designing a fuse, the terminals must be so arranged that it is impossible for an arc to form when the fuse "goes." This can be done by arranging the terminals sufficiently far apart. This should never be less than 1¼in., the distance increasing with the voltage. The curve below Fig. 3 gives the distance apart in inches for a given voltage. The fuse can also be improved by inserting a baffling plate (as in Fig. 2) between the terminals. Fig. 1 gives a type of fuse suitable for current up to 20 amperes

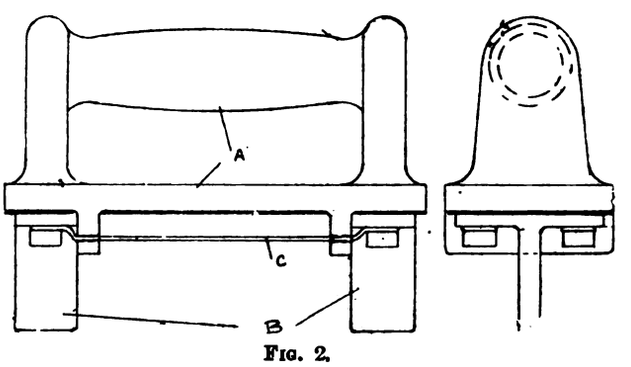

FIG. 2.

and 500 volts. Fig. 2 is more suitable for a lower voltage and heavy current: A, porcelain casting; B, terminals and male contacts; and C, the fuse wire. In the type shown two fuse wires may be used.

In Fig. 1, A is the terminal, shaping, or casting; B_1 B_2, asbestos disc; the centre ones, C_1 C_2, are half disc, so made for inspection; D, fuse wire; E, mica sheet rolled in the

Digitized by Google

form of a tube (glass may be used, but it is dangerous, as it might "fly" if a big short comes on). Mordey uses a glass tube with a dry powder in place of the asbestos.

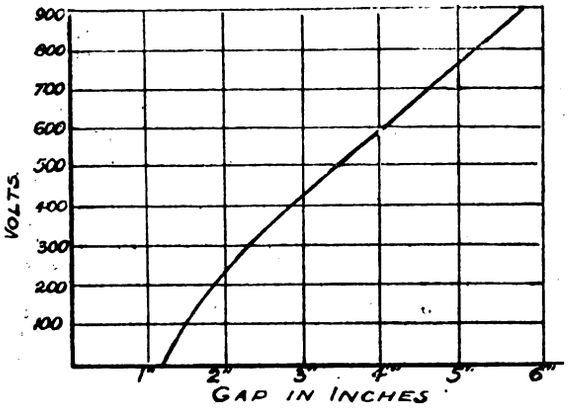

FIG. 3.

The powder will stop arcing This would not be practical for large fuses, so Weston places two fuses in parallel, one bare, the other, a small one, covered with powder. The larger one "blows" first, the small one stopping the arc. This, of course, will blow in turn, but the powder stops the arc. Table I. gives the *fusing* current of copper, tin, and lead wire; 25 per cent. must be taken off the fusing current to get a working current.

TABLE I.

Current in amps.	Copper. S.W.G.	Tin.	Lead.	Current in amps.	Copper. S.W.G.	Tin.	Lead.
1	47	36	35	60	21	11	10

40	23	14	13	300	13	5	4

T. W. S. H.

Answer to No. 378 (*awarded* 5*s.*)—The best material to make fuses of is undoubtedly pure copper wire, but in practice ordinary commercial tinned copper wire is found to meet all requirements. Fusible cut-outs composed of tin or lead and tin alloys are altogether unreliable and uncertain in their action, the reason being that the material in the course of exposure to the heating effect of the current, and to the deleterious action of the atmosphere,

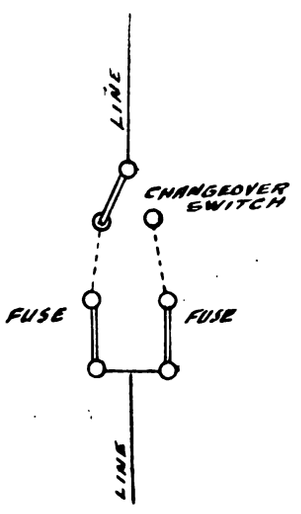

FIG. 1.

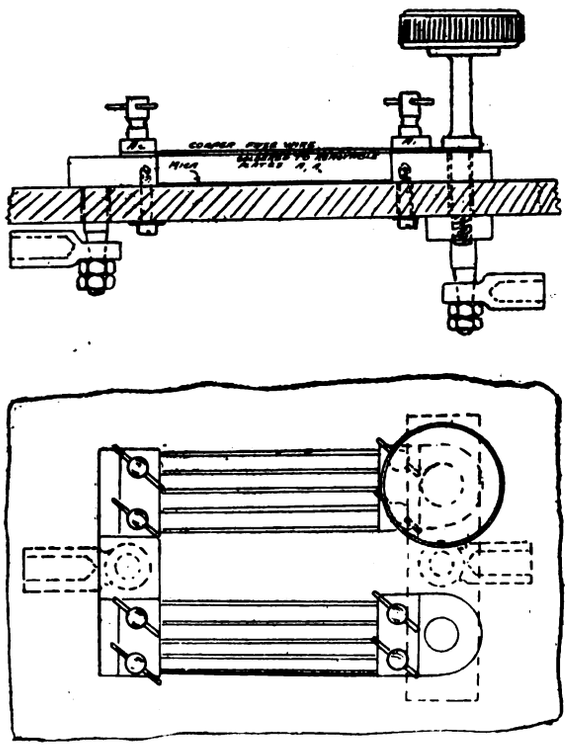
forms on its surface an infusible skin, which in its turn considerably raises the melting temperature of the fuse as a whole. It thus frequently happens that serious damage is done to the mains or armature coils before the current is broken. As the excess of current that a fuse will carry over and above that for which it has been calculated is an ever-varying quantity, depending upon local conditions, it is necessary to use a material which is only slightly acted upon by outside influences, and copper, as before mentioned, is found to be suitable in this respect.

In arranging fuses to carry large currents at 500 volts, the following points should be carefully attended to when fitting up on the switchboard: (*a*) The terminal blocks should be of ample section and contact area to avoid heating. (*b*) The fuses themselves should be arranged at the bottom of the board and protected from the marble or slate by a sheet of mica or other suitable material; by doing this damage from molten metal is not incurred. (*c*) The fusible material should be in several strands, and separated as far apart as possible to allow of cooling by means of the circulation of air. (*d*) In all cases fuses should be so designed to allow of easy and expeditious replacement.

A satisfactory method of doing this is to arrange the fuses in duplicate, connecting two terminals to one common sweating thimble and the two other terminals to the two connections of a change-over switch, as shown diagrammatically in Fig. 1. A combined duplicate fuse and two-way plug switch for heavy currents is shown in Figs. 2 and 3.



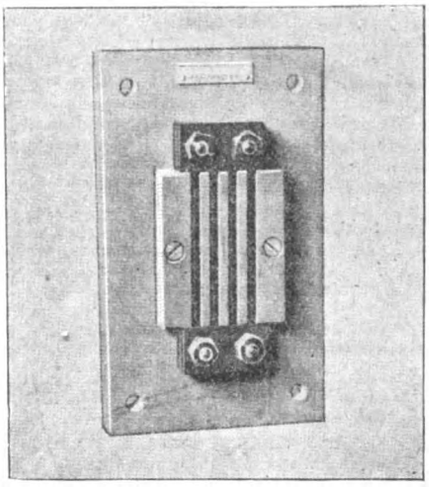
FIGS. 2 AND 3.

Assuming that the fuse is to be designed to blow at 400 amperes, the strands of copper wire being five in number, as shown in the sketch, each strand must, therefore, carry at the instant of fusing $\frac{400}{5} = 80$ amperes. The diameter of a copper wire to fuse at this current may be found from the formula $d = \left(\frac{C}{a}\right)^{\frac{2}{3}}$, where d = diameter of wire, C = current, a = constant, that for copper being 10,244.—F. H R.

Answer to No. 378 (*awarded* 5*s.*).—Lead and its alloys are being gradually discarded as fuse material in favour of copper. There are many reasons for this, some of which are as follows: Lead fuses always require the use of spring terminals, as with ordinary screw-down terminals the contact is certain to become loose owing to the alternate heating and cooling, as the current varies, and the non-elastic character of the lead. A lead fuse also deteriorates more rapidly than a copper one, partly due, perhaps, to a peculiar effect in large lead fuses—namely, that the metal in the interior of the fuse often assumes a semi-liquid state due to heating, the fuse only being prevented from blowing by the cooler outside crust. A copper fuse will also stand considerably more overload for a short time than a lead one, but will cut out equally well in case of a sudden short. Again, in small sizes, copper fuses are not so liable to be injured by stretching, etc., while being replaced in

Digitized by Google

a hurry, as are those made of softer metals. A very good form of multiple cut-out for heady currents is made by Messrs. Cowans, Limited, of Salford, of which a sketch is given. It consists of two massive terminal blocks on the usual enamelled slate base. Between these terminals is a slab of plain slate with four deep grooves in which lie the copper strands which form the fuse, one in each groove. The advantages of this form are that there is no great splash of molten metal when the fuse blows, and the enamelled slate is not injured, as it is protected by the grooved slab, and the arc is chilled at the instant of forming by the cold slate which surrounds it on three sides. This is, of course, a low-tension form of cut-out up to, say,



600 volts; other ingenious devices for higher pressures do not come within the scope of the question.—G. D. L.

PHYSICAL SOCIETY.

At the ordinary meeting held May 31, Prof. S. P. Thompson, president, in the chair,

A paper "**On the Resistance of Dielectrics and the Effect of an Alternating E.M.F. on the Insulating Properties of India-rubber**," by **A. W. Ashton** was read by Prof. Fleming. The author has obtained from his experiments formulæ for the charging and discharging currents of a condenser with rubber dielectric. The currents are exponential functions of the time. Curves for various potential differences have been plotted and were exhibited. These curves show that the insulating properties of rubber are increased by the application of high alternating E.M.F.'s. Prof. Fleming then read a note by Mr. Ashton '**On the Electrification of Dielectrics by Mechanical Means.**" A sheet of pure Para rubber was placed in a condenser, the plates of which were connected to a quadrant electrometer. A 2lb. weight was then dropped on to the condenser from a height of 3in. The electrometer received two impulses of opposite sign, one quickly following the other. The rubber was then stretched while in position, and a potential difference of seven volts was shown between the plates, the top plate being negative. The condenser and electrometer were then discharged, the sheet reversed, and the experiment repeated. The same effect was produced, the top plate again being negative. It appears, therefore, that polarisation of a dielectric being thus produced by mechanical energy, some part of the mechanical energy expended on the indiarubber during manufacture would remain in the dielectric as electric energy. "**A Model which Imitates the Behaviour of Dielectrics,**" by Prof. Fleming and Mr. Ashton, was exhibited by Prof. Fleming. The behaviour of dielectrics with regard to their residual charge is analogous to that of wires subjected to mechanical stress. A simple twisted wire is not, however, able to imitate all dielectric effects, and the present paper describes a model which represents things more completely. Six pistons separated by springs are placed inside a vertical cylinder. The bottom piston fits fairly tightly in the cylinder. The second piston fits slacker than the first. The third piston has a small hole in it, and each succeeding piston has a greater area cut away, the top piston having just sufficient metal left to make the spring come to rest without vibration after being compressed. The cylinder is filled with machine oil and vaseline. To the top piston is attached a rod, by means of which pressures can be exerted on the pistons for any length of time. This represents the charging of the condenser. The motion of the rod after releasing the weights represents the discharge of the condenser. This is registered graphically by a revolving drum, and the curves obtained are very similar to those from condensers with dielectrics.

Prof. Ayrton said he would like to know in what respect the model shown was superior to a strained wire. He had noticed about 10 years ago that alternating E.M.F. s appeared to improve condensers. He was then working with comparatively small voltages, and he was interested to know that Mr. Ashton, working with high voltages, had established the improvement. The deflection obtained by stretching the indiarubber sheet might be due to changes in temperature, the dielectric having a high thermo-electric power.

Mr. Price was glad that the question as to what actually might be called the resistance of a dielectric had been raised. There are two theories of residual charge—one due to Maxwell, and the other to Heaviside. The model exhibited represents Maxwell's theory. He considered that the electrometer experiment with the rubber dielectric favoured Heaviside's theory—that is, that the dielectric is composed of small charged bodies similar to the small magnets conceived to constitute a magnet. He expressed his interest in the fact that the top plate of the condenser was always negative.

Mr. Blakesley suggested putting a small hole in the bottom piston of the model, so that it might represent a condenser passing a small steady current. With regard to the stretched-rubber experiment, he said it would be interesting to make observations with the plates of the condenser vertical.

Mr. Campbell said he had made experiments, and found that the change in capacity of the rubber condenser affects the voltage sufficiently to mask the real effect.

Mr. Appleyard said it was important to have perfect contact between the dielectric and the metal plates.

It was pointed out by a visitor engaged in the cable industry that manufacturers are aware that pressure affects the insulating properties of guttapercha. Rubber is a mixture, and different rubbers behave differently under the action of alternating potential differences.

The **Chairman** said that if the quantity of electricity taken in on charging was equal to the quantity given out on discharge, then there could be no dielectric hysteresis.

The society then adjourned until June 14.

COMPANIES' MEETINGS AND REPORTS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

At the half-yearly meeting of the shareholders in this Company at the Cannon-street Hotel on Tuesday, **Major L. Darwin** stated that the object of the half-yearly meeting was to obtain their approval to the payment of an interim dividend; but it was usual on these occasions for the Board to take advantage of the opportunity, and to give some information as to the progress of the Company's business during the preceding six months. Since December last he was glad to say that, with the exception of guttapercha, the prices of raw material had eased, and the Company had been able to sell their manufactures at lower prices than had ruled for the previous 18 months. These reductions had, however, not been considerable. As a result of this, and of a general slackness in trade, their turnover did not compare favourably with the similar period last year. Within the last two months an improvement had taken place, and should this be maintained the Board hoped to meet the shareholders in December with a statement of affairs showing much the same results as they submitted six months ago. The Company had just completed the laying for the Commercial Cable Company of a cable between Weston-super-Mare and Waterville, in Ireland, and their steamer "Buccaneer" had just terminated her charter to the Western Telegraph Company. Owing to the continued state of unrest in South Africa, their agency in Durban and that in Buluwayo had not yet been able to do any profitable work, but the Board hoped that when hostilities ceased the Company would be fully prepared to take advantage of every opening for business which might present itself. The market prices of the different grades of guttapercha were lower than they were recently, but the quality of these grades was below the usual standards, with the net result that buyers got less useful material for the money they paid than was formerly the case. To enable the Company to increase the facilities for production at their French works, the Board had just completed the purchase of a small neighbouring property. This purchase became a necessity, as during the last three or four years they had been much hampered for want of room. In conclusion, he moved the declaration of an interim dividend of 2½ per cent., or 5s. a share.

Mr. A. Scott seconded the motion, which was carried unanimously.

ELECTRICAL POWER DISTRIBUTION.

The ordinary general meeting of this Company was held on Tuesday at the offices, Surrey House, Victoria-embankment, under the presidency of Mr. W. L. Madgen, managing director.

The **Chairman**, in moving the adoption of the report and accounts (which appeared in our last week's issue), said the Board fully expected that the rate of profit which had accrued to them during the past nine months would be maintained. He wished to call attention to an item on the credit side of the balance-sheet as expenditure on Power Bills and new schemes—viz., £16,840. The directors felt that this amount was fully justified by the value of the schemes now being developed. The attention of many would no doubt have been drawn to the vast strides which had been made in connection with electrical work in America, on the Continent, and in our own Colonies. That progress had been relatively more rapid than it had been in this country, but many of them

Digitized by Google

felt some years ago that the time had arrived when there was good promise of similar undertakings in connection with electrical power distribution proving remunerative in this country. It seemed, indeed, necessary in the interests of the country that something should be done to give our industries the same facilities as those which similar industries were enjoying abroad. The Electrical Power Distribution Company went to work and they had obtained a very fair measure of success. In the session of last year four Electrical Power Bills were passed through Parliament. Of these this Company secured two and for districts which he thought were exceptionally favourable – viz., the county of Durham, one of the greatest industrial areas in the country, and the north metropolitan district, which had exhibited during past years an enormous increase in population in the residential districts, and had also in more recent years shown a tendency to industrial development along the banks of the River Lea. The cost of these two Power Bills was included in the item to which he had alluded. In addition to these the Company had secured rights for electricity supply in numerous other districts, particulars of which were given in the appendix to the report. These latter undertakings, of course, would not in themselves offer such a large scope for investment as the Power Bills, but in some cases they were the nucleus of what might be equally large undertakings later on. No time was lost after these two Power Bills passed through Parliament, and the work was immediately put in hand. Last month the Company successfully inaugurated the main power station of the Durham scheme at Gateshead. The British Electric Traction Company had in that district the beginning of a very extensive electric tramways scheme, and the first business of the power station was to supply these tramways with electric current. The general electricity supply for the town of Gateshead and neighbouring districts was making very rapid progress, and the directors were led to believe that their confidence in the suitability of the districts for power purposes would be well justified. With reference to the North Metropolitan scheme, there would be two power stations, both on the River Lea, where facilities for coal and water supply were best. During the present month the second of these power stations would be inaugurated at Hertford. In Barnet the supply of electricity had already been inaugurated, and the number of consumers was steadily increasing from week to week. Concessions had been obtained in this district for light railways, and these would be worked in connection with the electricity supply. The construction of these light railways would be commenced in the autumn of the present year. Most of the other works referred to in the report would be completed during the present year, and the directors confidently believed that a very profitable business would be done. It was the one object of the Company to bring the electricity supply in this district within the reach of all classes, and to adopt methods to this end. There were clear indications not only abroad, but already in this country, that the era of separate generating stations, one for each town or district was passing away, and that the era of electrical power distribution on a large scale was now beginning. The operations of this Company placed them directly in this line of development, and the Board felt pretty confident that they had made a good start, and that the Company would derive a large measure of success in the business which had already been inaugurated, and that which they had taken steps to inaugurate in the years to come. In conclusion, he moved the adoption of the report and accounts.

Mr. E. P. Sellon seconded the motion, which was agreed to without discussion.

Mr. Emile Garcke and Mr. J. S. Raworth having been re-elected directors, the meeting closed.

At an extraordinary meeting held immediately afterwards several alterations in the articles of association were agreed to.

MIX AND GENEST, LIMITED, OF BERLIN.

The twelfth annual meeting of shareholders was held on May 18, when a most satisfactory balance sheet was submitted. The gross profit has amounted to £55,400, of which £17,750 were absorbed by income tax, salaries, and general expenses, £11,700 were written off for depreciation on plant, tools patents, and premises, thus leaving a net profit of £25 950, out of which a 14 per cent. dividend has been paid to the shareholders. In the report of the directors the continued progressive movement in the development of the concern was emphasised, especially the fact that during the last year the contracts placed by the Government Telephone Department with the firm for multiple switchboards and telephone instruments had been of considerable magnitude. All departments had not only been fully occupied, but in a good many instances overtime had to be worked to cope with the increasing orders. No less than 1,700 hands are at present employed, and although the new factory has only been built within the last four years, additional land had to be acquired in order to allow of further extensions, which when completed will cover an area of nearly 10,000 square metres. The prospects for the present year are considered to be highly promising, as evidenced by the considerably increased turnover as compared with the corresponding months of the previous year.

MEXICO ELECTRIC TRAMWAYS.

The fourth ordinary general meeting of the shareholders was held on Wednesday at Winchester House, E.C., Colonel Sir Euan-Smith, chairman, presiding.

In moving the adoption of the report, the **Chairman** said the main fact that had to be recognised was that the Company had had to contend with very great difficulties during almost the whole of the past year. Under these circumstances the Board was of opinion that the shareholders might be congratulated on their having earned the dividend which the Board now recommended, and which exceeded that of last year, for owing to the sewage operations in the city of Mexico it had taken their officials all their time to carry on the tramway services with punctuality and efficiency, and still more to make the service pay a satisfactory dividend. That was the main fact that had to be considered in connection with the operations of the past year, and that, coupled with the commercial depression under which the country had been labouring, might be regarded as having had the minimum possible injurious effect upon the dividend. The relaying of the track, the extension of the electrical system, the erection of the necessary power-houses and other buildings, and the provision of the required rolling-stock, was being proceeded with in a satisfactory manner, and they confidently looked forward to giving the shareholders each successive year a better, and still better, account of the progress of the operations. Since the commencement of the current year (1901) the Board had concluded a most advantageous arrangement, which had had the effect of leasing the whole lines of the Ferrocarriles Company to the Mexico Electric Tramways, Limited, under which name the operations of their Company would be henceforth conducted in Mexico.

Mr. Ludwig Breitmeyer seconded the motion, which was carried unanimously.

Vice-Admiral A. H. Markham and Mr. A. Parrish having been re-elected directors, a resolution adopting the dividends recommended was agreed to.

A vote of thanks to the chairman concluded the proceedings.

APPOINTMENTS VACANT.

Tramways Manager, South Lancashire Tramways Company. Details in our advertisement columns.

Charge Engineer, city of Bristol electricity department, £3 per week. Details in our advertisement columns.

Assistants (Two), Birkenhead Corporation electric tramways, 30s. per week, June 11. Apply to Mr. W. Bates, borough electrical engineer.

Instructor in Electric Wiring Classes, two evenings per week, Battersea Polytechnic, £35 per session. Details in our advertisement columns.

Mains Assistant and Draughtsman, Islington borough electricity department, £2 per week, June 11. Details in our advertisement columns.

Assistant Engine-Driver, Islington borough electricity department, 7½d. per hour, 56 hours per week, June 11. Details in our advertisement columns.

Meter Inspectors, borough of Nelson, 30s. per week, June 15; Bradford, accustomed to Ferranti, Thomson, and Bastian meters preferred, 30s. per 50-hour week. Details in our advertisement columns.

Student Demonstrator in Mechanical and Electrical Engineering, for session September to July, part time only, Battersea Polytechnic, £50. Details in our advertisement columns.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Glasgow.—The Corporation invite tenders for the supply of electricity meters. Tenders by June 10. Details in our advertisement columns.

Islington.—The Lighting Committee invite tenders for free or assisted wiring. Tenders by June 11. Details in our advertisement columns.

Glasgow.—The Corporation invite tenders for the supply of branch rubber-covered cables. Tenders by June 10. Details in advertisement columns.

Edinburgh.—The Corporation invite tenders for ash-conveying plant, Dewar-place station. Tenders by June 15. Details in our advertisement columns.

Walthamstow.—The Urban District Council are prepared to receive tenders for electric lighting meters (ordinary penny-in-the-slot). Tenders by June 14.

Sutton Coldfield.—The Corporation invite tenders for meters (direct-current) and cut-outs. Tenders by June 15. Details in our advertisement columns.

Ipswich.—The Corporation invite tenders for the supply, delivery, and erection of dry-back marine-type boilers. Tenders by June 8. Details in our advertisement columns.

Wigan.—The Electric Light and Tramway Committee invite tenders for 12 double-deck single-truck electrical cars. Tenders by June 18. Details in our advertisement columns.

London, E.C.—The East Indian Railway Company invite tenders for electric overhead travelling cranes, etc. Specification may be seen at the Company's Offices, Nicholas-lane, London, E.C. Tenders by June 12.

Islington.—The Lighting Committee invite tenders for the painting of the arc lamp columns and crutches, of which 298 are

Digitized by Google

in use in the borough. Tenders by June 11. Details in our advertisement columns.

Peterborough.—The Corporation invite tenders for the supply and erection of one Lancashire boiler, 30ft. by 8ft., and one 120-kw. steam dynamo. Tenders by June 14. Details in our advertisement columns.

Exeter.—The Town Council invite tenders for erection of the buildings of their new electricity generating station. Specifications, etc., may be obtained from Mr. Donald Cameron, city engineer and surveyor. Tenders by June 14.

West Ham.—The Council invite tenders for two 500-kw. continuous-current tramway generators, coupled direct to three 850-i.h.p. steam engines, and 11 water-tube boilers. Tenders by June 25. Details in our advertisement columns.

Christiania.—The Government Railways invite tenders for 37,600 ko. 4mm. galvanised iron wire, 9,300 ko. 3mm. galvanised iron wire, 12,800 insulators, etc. Tenders by June 26. Particulars, etc., at the office, Jernbanetorvet 8-9, Christiania.

Madrid.—The Public Works Department of the Department of Agriculture, Madrid, invite tenders for the construction and working for 60 years of an electric tramway from Santiario de la Yedra to Balza. Tenders by July 26. Particulars at that office.

Edinburgh.—The Corporation invite tenders for the electric lighting installation, etc., of the first portion of the Colinton Mains Fever Hospital, the number of lighting points being about 1,550. Tenders by June 12. Details in our advertisement columns.

Rotherham.—The Corporation invite tenders for the wiring of the police buildings preparatory to a supply of electricity from the Corporation mains. Specification, etc., may be obtained from the borough electrical engineer, Mr. E. Cross. Tenders by 20th inst.

Leith (Scotland).—Tenders are invited for the supply and erection of one Sinclair's No. 1 Lancashire boiler and additional steam-piping at the electricity works. Specification, etc., may be obtained from the Burgh Electrical Engineer. Tenders by 12th inst.

Exeter.—The Council invite tenders for boiler-house equipment, pipes, etc., engine-room equipment, switchboards, connecting cables, coal bunkers and conveyors, and feed and condensing water tanks. Tenders by June 14. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for the supply and erection of a switchboard at their electricity works, Valley-road, Bradford. Specifications, etc., may be obtained from Mr. R. A. Chattock, M.I.E.E., city engineer, Town Hall, Bradford. Tenders by 13th inst.

West Ham.—The Town Council invite tenders for the construction of three transformer chambers in Bridge-road, Stratford, Great Eastern-road, Forest Gate. Specification, etc., may be seen at the Borough Engineer's Office, Town Hall, West Ham, E. Tenders by 11th inst.

Wigan.—The Electricity Committee invite tenders for one complete direct-reading potentiometer, one ditto photometer, tramcar spare wheels, ditto pit jack, car body lifting jack, and one complete Thomson's balance. Tenders by June 12. Details in our advertisement columns.

Taunton.—The Corporation invite tenders for the construction, supply, and erection of one 250-kw. steam alternator, one 15-kw. motor-generator, switchboard extensions, one water-tube boiler, superheater, jet condenser, and air-pump, and sundry pipe extensions. Tenders by June 11. Details in our advertisement columns.

Burnley.—The Electricity Committee invite tenders for (A) five injectors, capable of dealing with 700 gallons per hour; (B) one feed pump, capable of dealing with 3,500 gallons per hour. Specifications, etc., may be obtained on application to Mr. Robt. Birkett, the borough electrical engineer, Aqueduct-street, Burnley. Tenders by June 10.

Barking Essex).—The Urban District Council invite tenders for the supply and erection of condensing plant, comprising surface condenser, cooling tower, electrically-driven air and circulating pumps, steam grease extractor pipework. Full particulars, etc., may be obtained from the Engineer, Electricity Works, East-street. Tenders by June 19.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

Kearsley.—The Urban District Council invite tenders for the taking-up roadway and repaving, laying of rails, points, etc., and all labour required for the construction and completion of tramways from Market-street to Unity Brook and along Longcauseway at Kearsley. Specifications, etc., may be seen at the office of the Council's surveyor, Mr. Herbert Nuttall, A.M.I.C.E., 20, Market-street, Bury. Tenders by June 13.

London, S.W.—Tenders are invited for the supply of 13,400 tons of steel rails and 958 tons of fishplates for the Queensland Railways. Tenders will be received at the Queensland Government Office, 1, Victoria-street, London, S.W., until 2 p.m. on June 11, endorsed "Tender for Steel Rails and Fishplates," and accompanied by a preliminary deposit of 1 per cent. on the tender. Specifications, drawings, etc., may be obtained at the office of the Agent-General for Queensland.

York.—The North-Eastern Railway Company invite tenders for the following articles, in such quantities as they may require, during six months ending Dec. 31, 1901, delivered carriage paid at the telegraph stores at York: (1) telegraph apparatus; (2) telegraph wire and line stores. Particulars may be obtained on application to Mr. Graves, Telegraph Department, York. Tenders by June 10.

Warrington.—The Corporation invite tenders for the supply, delivery, and erection of one water-tube boiler and pipework; supply, delivery, and erection of 500-kw. high-speed engine of the Willans type, with direct-coupled continuous dynamo; and supply, delivery, and laying of underground mains, stoneware conduits, etc. Specifications, etc., can be obtained at the offices of Messrs. Preece and Cardew, 13, Queen Anne's-gate, Westminster, S.W. Tenders by June 13.

Uganda.—The Crown Agents for the Colonies, acting on behalf of the Uganda Railway Committee, invite tenders for the supply of galvanised iron wire, specification and form of tender for which can be obtained on application to the Crown Agents, at whose office the drawing will be on view between the hours of 10 a.m. and 4 p.m. (Saturday, 10 to 2). Tenders to be delivered, addressed to the Crown Agents for the Colonies, Downing-street, S.W., and endorsed "Tender for Galvanised Iron Wire, Uganda Railway," not later than noon on June 11.

Mansfield.—The Corporation invite tenders for the supply and erection of—boiler-house plant: three Lancashire boilers, mechanical stokers, steam pumps, economiser, and motor; engine-house plant: three 200-kw. high speed steam generators, motor transformer, balancing motor transformer, and accessories; Korting condensers and electric pumps, switchboard and instruments, accumulators, overhead travelling crane, electricity supply mains; public lighting: arc lamps, posts, and accessories; meters, and workshop equipment. Tenders by July 12. Details in our advertisement columns.

Erith.—The Urban District Council invite tenders for the supply and erection of two Lancashire boilers, with fittings, economiser, feed pumps, etc.; pipework, etc., in engine and boiler house; surface-condensing plant, three steam alternators (vertical enclosed high-speed engines direct coupled to three-phase alternators), main switchboard and connections, 10-ton engine-room travelling crane, transformers, sub-stations, and equipment, underground mains, conduits, roadwork for private and public lighting, arc lamps (open type), posts, and station lighting. Tenders by June 24. Details in our advertisement columns.

RESULTS OF TENDERS:

Barnsley.—The Town Council have accepted the tender of Kenworthy, Taylor, and Co. to supply electric light service boxes.

Aberdeen.—The Tramways Committee have accepted the tender of J. Leith, jun., for the execution of the work in Great Western-road.

Lancaster.—The Corporation have accepted the tender of the British Westinghouse Electric and Manufacturing Company, at £2,220, for a 200 kw. set of engine and dynamo.

Dundee.—The Tramways Committee have accepted the tender of the International Electric Company, Leeds, at about £4,000, for a new engine and dynamo for the electric station.

London and India Docks.—Mr. G. W. Clarke, of London, Harold Wood, and Grays, has been awarded the contract for the supply of incandescent lamps for the coming year to the Dock Company.

Woolwich.—The Borough Council have accepted the tender of Messrs. Smith and Son, London, at £40,574 (foundations £6 437 and station £34,137), for the electricity and destructor station, Plumstead.

Islington.—The Guardians have accepted the tender of Julius Sax and Co., Limited, of 51, Rupert-street, W., for additional telephones at £44, and for lighting the carriageway inside the grounds from the front gate at £178.

Trafford Park.—The Electrical Company, Limited, 122 and 124, Charing Cross-road, W.C., have obtained an order from Messrs. Browett, Lindley, and Co., Limited, for one direct and three-phase current dynamo, with one armature, 600 kw. on either side, for Trafford Park electric light and power station.

Shoreditch.—The Borough Council have accepted the following tenders: The Renewable Lamp Company, for the supply of incandescent electric lamps for the period ending March 31, 1902; W. and T. Henley's Telegraph Works Company, Limited, for the supply of the necessary cable required for the extension of mains during the next nine months, £10,516. 5s.

Middlesbrough.—The Corporation have accepted the following tenders in connection with the extensions to the municipal electricity works, subject to the sanction of the loan by the Local Government Board: (Section A) Holdsworth and Sons, boiler-house plant—one 30ft. by 8ft. 6in. Lancashire boiler and accessories, £915. 10s.; (B) Witting Bros., Limited, engine-house plant—one 300-kw. high-speed steam generator (Browett engine and Kolben dynamos) and pipework, £3 564; (C) Crompton and Co., Limited, condensing apparatus—ejector condenser, with circulating pumps, £557; (D) British Insulated Wire Company, Limited, underground work—cables, troughing, trenching, and boxes, £737. 10s. 2d.

Bristol.—The following contracts have recently been let in connection with the Avonbank electricity works of the City Council: E. Nuttall, Manchester, foundations, retaining walls, culverts; R. Wilkins, Bristol, buildings; Babcock and Wilcox, London,

Digitized by Google

boilers and coal conveyor and elevator; E. Benniss, Bolton, coal-discharging plant; Bumsted and Chandler, Hednesford, induced-draught plant; G. J. Weir, Cathcart, Glasgow, steam, electric, feed, and general service pumps; Doulton and Co., Lambeth, water-softening plant; Higginbottom and Mannock, Manchester, electric travelling crane; Siemens and Willans, steam alternators and steam dynamos; W. H. Allen and Sons, Bedford, condensing plant; Babcock and Wilcox, steam and other piping. General—British Electric Transformer Company, London, alternating-current transformers; E. Nuttall, underground sub-station; S. Z. de Ferranti, Hollinwood, low-tension switchboard at Temple-back works.

Bradford.—The Corporation have received the following tenders for the construction and erection of a five-ton electric travelling crane for their new tram depôt, Leeds-road, Thornbury, to operate on a 500-volt direct-current circuit:

Thornton and Crebbin, Bradford (accepted)	£355
Higginbottom and Mannock, Crown Ironworks, Manchester	468
Witting Bros., Limited, 49, Cannon-street, London	520
Witting Bros., Limited	618
Isles, Limited, Steam Crane Works, Stanningley, Leeds	520
J. Booth Bros., Limited, Rodley, Leeds	525
T. Smith, Rodley, Leeds	550
Jessop and Appelby Bros., Limited, Leicester	580
J. Carrick and Sons, Limited, Dalry Ironworks, Edinburgh	685
British Schuckert Electric Company, Limited, Clun House, Surrey-street, Strand, London, W.C.	658

BUSINESS NOTES.

TRACTION.

Isle of Man.—It is expected that the Isle of Man tramways undertaking will shortly be sold.

Nottingham.—It is hoped to have the Basford section of the electric tramways finished by July 1.

Greenock.—The electric cars will probably be running between Cathcart-street and Gourock by July 1.

Aberdeen.—An extended service of tramcars was put on all the routes of the Corporation tramways on Saturday last.

Wigan.—Major Druitt, Board of Trade inspector, has inspected the new electric tramway between Wigan and Boars Head.

Blackburn.—Major Druitt has held an enquiry on behalf of the Board of Trade into the tram collision at Ewood on March 27.

Huddersfield.—By the large majority of 3,183 the people of Huddersfield have decided to have a service of trams on Sundays.

Motorcar Goods Service.—A motorcar service for the conveyance of goods between London and Tunbridge Wells will start to-day.

Bristol.—The total number of passengers carried on the tramway company's system during the week ended 31st ult. was 1,118,784.

Continental Scheme.—The proposed new electric railway from Zermatt to Zinal, costing £240,000, and passing through some of the most beautiful Alpine scenery, is about to be commenced.

Uxbridge.—The Board of Trade have granted the London United Tramways Company an extension of time for two months in connection with the light railway extensions in the district.

Berlin.—The Berlin municipal authorities are reported to have granted £1 000 for the preparation of a plan for an underground railway, which is to run from north to south of Berlin, following the line of the Friedrichstrasse.

North London Electric Underground.—It is expected that the tunnel work in connection with the Great Northern and City deep-level electric railway from Finsbury Park to Moorgate-street will be finished by the end of this year.

Wednesbury.—The Corporation have decided to appoint an engineer, "or other fit person nominated as referee by the Board of Trade," to value that portion of the South Staffordshire tramways which they are now entitled to purchase.

Portsmouth.—The Town Council have decided to create a new 3 per cent. redeemable stock to an amount not exceeding £610,000, this sum being required for the purchase of the local tramways and the equipment of the lines for the electric traction.

Blackpool.—The new Marton section of the Corporation electric tramways, which was opened a week ago, has proved very popular. The receipts for the first five days were about £240, but of this the receipts on Monday and Tuesday alone were £202

Glasgow.—The Tramways Committee have had under consideration reports by Mr. John Young, general manager of the tramways, on the progress being made at the Pinkston power station, and on accidents and the rate of speed of electric cars. The reports have been generally approved.

Bournemouth.—A largely-attended meeting has decided to oppose the Corporation's Tramway Bill as a protest against the proposal to take away a portion of the north-west corner of St. Peter's Churchyard for the purposes of widening the road at that point in connection with the tramways scheme.

Halifax.—The Tramways Committee have resolved on several alterations in the tramcar service with a view to effecting a material saving in the weekly expenditure. These alterations include a reduction in the number of cars on certain of the routes, and the adoption of an earlier hour for the last car to the out-districts.

Cheltenham.—At the last Town Council meeting, the Electrical Engineer reported that he had tested the first steam dynamo for traction purposes, and the results were satisfactory. All the cables for the tramway had been delivered, and a good start made with the laying of them, and he hoped to complete the laying in a fortnight.

Rochdale.—At a meeting of the Tramways Committee it was reported that a quantity of the rails to be used in Rochdale had been tested and found very satisfactory. Plans of the proposed tramshed and offices at Bridgefold were approved subject to certain slight alterations. It is expected that the actual work of laying the lines will commence on the Norden section next week.

Ipswich.—The chances of an agreement as to the price of the purchase of the tramway system by the Corporation being remote, the parties have had recourse to arbitration. Sir Fredk. Bramwell sat at the Surveyors' Institute this week, when evidence was taken on behalf of the tramway company. The further hearing was adjourned *sine die*.

Pontypridd.—The Board of Trade have granted a provisional order to the Urban District Council for the construction of electric tramways in the district. The aggregate length of the new lines will be just over three miles. While power is given to the Council to enable them to work these tramways, they have no authority to construct any station for generating electrical power. A clause is also inserted to protect the property of the Cardiff Corporation, including the Taff Fawr water-mains.

Burnley Tramways Purchase.—In connection with the acquisition of the undertaking of the Burnley and District Tramways Company, the balance of the purchase-money, with interest and costs, amounting to £51,000, has just been paid to the company's solicitors by the various local authorities concerned. The money will be handed over to the shareholders of the tramway company in perhaps a couple of weeks, and the directors have given it out that the share money will be paid in full—20s. in the pound—with (as usual) 5 per cent. interest.

Glossop.—The Board of Trade have granted a provisional order to the Urban Electric Supply Company, Limited, for the construction of a system of electric tramways in the borough. The main line of the authorised system will be just four miles in length. From the main line a short line will be constructed just over half a mile in length. The tramways will be laid as single lines, with the necessary passing places, on a gauge of 4ft. 8½in. The right of purchase by the Corporation is not to be exercised until the expiration of 57 years from June, 1900.

East London Electric Trams.—It is announced that the East Ham electric tram system, which is owned by the local District Council is practically completed, and that the trams will be running in the course of a few days. The system runs from Manor Park to North Woolwich, through East Ham and Becton, and will join when completed, with the Ilford Council's projected system at one end and the West Ham Corporation's system at the other. When the joint schemes are completed there will be a network of trams more than 30 miles in extent in East London.

Darwen.—At the last Town Council meeting, a resolution was proposed that "in view of the serious financial position of the borough, the surveyor be instructed not to make any further contracts in connection with the Hoddlesden tramways before the next Council meeting, and that in the meantime a special committee be appointed to enquire and report upon the extent to which the Corporation is already committed by contracts in the matter and the probable cost of rescinding the same." After some discussion, the motion was defeated by a large majority.

District Railway.—A company is about to be formed to carry out the work of converting the District Railway Company's system to electric traction. This company, which is known as the Metropolitan District Electric Traction Company, Limited, proposes to lay down the new permanent way, provide the new rolling-stock, and erect a generating site. A site for the station has been selected at Lots-road, Chelsea and it is understood that when complete the premises will be leased by the traction company to the railway company at a rent based on a percentage of the expenditure.

Brighton—At the last meeting of the Town Council the Works Committee again brought up the matter of the extension of Volk's electric railway east of the Paston place groyne. They reported that Mr. Volk had had an interview with them, and had expressed his willingness to give up the connecting piece of line across the Madeira-road lawn and the Paston-place groyne, the terminus of the present line remaining unaltered, and the new part to commence from the eastern part of the groyne, provided the Corporation agree to waive their right to determine the license within the first seven years. The committee recommended that Mr Volk's offer be accepted.

Glasgow.—The result of working the tramways in the financial year just ended shows that since 1895 the takings have gone up no less than £156 000 For the past year the earnings amounted to £484 900, or £20 000 more than in the previous 12 months. Half of this increase has been secured since the Glasgow Exhibition opened on May 2. The weekly advances top £2,000, and as electric traction has been introduced within the last three weeks, it is expected that far larger profits will be secured during the ensuing year. At the Eastern Police Court last week a tram driver in the employ of the Corporation was fined a guinea or seven days' imprisonment on the charge of "reckless driving."

Bavarian Electric Railways.—A demonstration recently took place on the Palatinate (Bavaria) railways of the system of electric

Digitized by Google

traction which has been introduced for the purpose of affording a means of communication between suburban localities and the stations at which the express trains stop for the reception of passengers. The first two trial sections were between Ludwigshaven and Neustadt, a distance of 20 miles, and between Ludwigshaven and Worms, 14 miles separating these two towns. The system of traction in use is the storage battery method, there being four long coaches, each of which can travel separately, or any combination can be made in the form of a train with trailer cars when necessary.

Epping Forest.—It is reported that an application is about to be made by the North Metropolitan Tramways Company to the Light Railways Commission for an order authorising the construction of a network of tramways, to be known as the Tottenham, Walthamstow, and Epping Forest Light Railways. The proposed route starts from Tottenham, and runs through Walthamstow, Leytonstone, Wanstead, Snaresbrook, Woodford, and Buckhurst Hill. It is felt that if the application of the tramway company is granted the natural beauty and solitude of a large tract of the Forest will be destroyed, and a public meeting of property owners and prominent gentlemen residing in the neighbourhoods affected by the scheme has decided to strenuously oppose the application.

Taunton.—The workmen engaged in excavating the roads preparatory to the laying of the lines for the new electric trams have gone out on strike, and the work is completely at a standstill. The men were being paid at the rate of 4½d. per hour, and they demanded 6d. The contractors offered 5d., but this was refused. Great inconvenience is experienced from the state of the roads, and a large part of the excavations have been filled in. The British Electric Traction Company, who are carrying out the undertaking, are under an agreement with the Town Council to complete the tramways by Aug. 1. The Council have agreed to supply the electric power, and are applying to the Local Government Board for sanction to a loan for making the necessary extension of plant at their electric light depôt.

Accrington.—At the Town Council meeting on Monday, it was stated that the provisional agreement entered into with the British Electric Traction Company was to have expired on the 31st ult. A suggestion was then put forward that if the agreement had really lapsed the Corporation should negotiate with the tramways company for the resumption of the portion of the lines now leased to the company and worked by them, with a view to this section being converted from steam to electric traction. It was further explained that Accrington could not obtain possession of the whole of the tramways undertaking owing to the fact that Haslingden and Rawtenstall Corporations had signified their intention of buying the portions of the lines within their respective boroughs. The consideration of the matter was deferred.

Birkenhead.—The extension of the electrical tramways system in the borough is proceeding apace. The New Ferry route is already very popular, and a source of substantial income. For the four weeks ending May 19 the total number of passengers carried was 189,803 on that section. The Tramways Committee passed a resolution some time ago directing that application be made to the Board of Trade for sanction to the borrowing of £21,700 for the conversion of a single tramway track into double tracks and the construction of passing places. It is now proposed to rescind that resolution, and that the sum of £9,902 be the amount borrowed for a similar purpose, but with a more limited estimate. The Council will also be asked to sanction applications for the borrowing of £13,000 for the provision of 15 additional cars, and £7,500 for the purchase of extra electrical generating plant.

Sunderland.—Experiments with a new form of lifeguard are at present being made on one of the Corporation tramcars. We take the following description of the device from the local Press: In the front of the car is a piece of wirework stretching right across the front. This is placed vertically, and moves up and down at the will of the driver. Underneath, in place of the customary horizontal fender, is one which, though ordinarily horizontal, can be dropped down by the driver. Therefore, in the event of the vertical wirework not preventing the person getting under the car, it would be next to impossible for anyone not to be picked up by the fender underneath. The apparatus is called Wilson and Bennett's patent automatic lifeguard, and it is made by Messrs. Gabriel and Co., of Birmingham. The takings on the whole system of tramways for Monday and Tuesday in Whit week are put down at £700.

Manchester.—The Board of Trade have given their formal approval of the opening of the Cheetham Hill and Hightown routes of the Corporation electric tramway system for public traffic. The principal condition which is laid down relates to the speed at which the cars shall be run. Four different speeds are mentioned. The cars may not travel round curves at more than four miles an hour, along crowded streets at more than six miles an hour, along moderately busy streets at more than eight miles an hour, and along suburban streets at more than 10 miles an hour. With regard to the equipment, the Board of Trade suggests a slight alteration in the lifeguard at the front of each car. This is fixed so as to be about 3in. above the roadway. The Board of Trade fully approves of the form of guard adopted, but suggests that it would be more efficient if fixed a little lower. The cars will be available for public use to-day.

Barcelona Tramways.—The net profit for 1900, including £1,211 brought forward, is £22,120. The service of the debentures and debenture stock absorbs £10,264, the dividend on the preference shares £5,000, and after deducting the loss on realisation of stud and the suspense account, there remains £317 to carry forward. The directors regret that the accounts do not enable them to recommend a dividend on the ordinary shares. The grant of the concession for working the Ensanche system by electricity is now only subject to certain formalities. When these are settled, the directors hope to enter into a lease or working agreement to the mutual advantage of both companies. A new concession, to be worked by electricity, has been obtained for an extension of about 1½ miles of one of the company's principal lines. This, the Board is satisfied, will be of considerable value, and the work of construction will be taken in hand without delay.

Sheffield.—The most forward section of the Corporation tramway extensions is that from Broomhill to Ranmoor. The length of the route is 1,400 yards, and the greater part of the track has already been laid. The line is single, with loops. Cable pipes are now being put down; the cables will be laid shortly, and the fixing of the overhead equipment will not be a long undertaking. It is expected that the route will be ready for passenger traffic by the end of this month. As soon as this extension is finished, a start will be made with the work of carrying the lines further forward to Nether Green—a distance of 800 yards—and it is expected that this will occupy six weeks. The Ecclesall section is also to be extended to Nether Green, by way of Rustlings-road, and a beginning has been made with the sewer work in that thoroughfare preparatory to the laying of the lines, which will be proceed with shortly. Good progress is being made with the extension to Intake village. An official statement shows that the traffic receipts for the week ended 2nd inst. amounted to £4,590, or nearly £1,000 in excess of the takings during Easter week, which amounted to £3,670. Last April it was anticipated that an average of £3 000 a week might be relied upon. In face of last week's, however, it is assumed that before very long an average of £4,000 a week will be reached, representing more than £200,000 per annum.

Baker-street and Waterloo Railway.—In their report to the creditors and shareholders of the London and Globe Finance Corporation the liquidators state in reference to the Baker-street and Waterloo Railway that up to the present Messrs. Perry and Co., the contractors for the construction of the line, have continuously carried on the works, and the same are now in progress, and a considerable portion of the tunnelling between Baker-street and Waterloo completed, the payments for same being provided by the railway company out of the funds in its possession. The report proceeds: "We desire to point out that the purchasers of this line, in addition to the provision of the sum of £500,000 before referred to, will become responsible for the completion of the line from Baker-street to Waterloo, together with the extensions from Paddington to Baker-street and Waterloo to the Elephant and Castle, thereby incurring a liability for an additional sum of over £1,500,000." In conclusion, the liquidators state that whether or not a sale is effected as a result of the negotiations which have been proceeding, they are of opinion that the corporation's interest in the railway will be sold sooner or later. They are satisfied that there are several parties who would be prepared to purchase, but at a price which in the interest of both creditors and shareholders ought not to be accepted because of its insufficiency.

LIGHTING AND GENERAL.

Rotherham.—It is proposed to extend the electric light cable to Moorgate.

Sculcoates.—The question of electric lighting generally of the workhouse is being considered.

Rathmines.—The Urban District Council have fixed the rate to be charged for current at 4½d. per unit.

Hoylake and West Kirby.—The electric lighting works at Hoylake will be opened on the 8th inst.

Share Market.—Taken as a whole, electric shares were firm during the week, with but little change.

Crewe.—The Town Council will apply for sanction to borrow a further sum of £5,000 for electric lighting purposes.

Birkenhead.—The salary of Mr. W. Bates, the borough electrical engineer, has been increased by £100 per annum.

Commercial Cable Co.—The directors have declared a quarterly dividend of 1¾ per cent. on the capital stock, payable July 1.

Sunderland.—The borough electrical engineer's last report shows a profit of £1,257 on the electric light undertaking for the past year.

Limerick.—The Town Council have decided to ask the Board of Trade for a further extension of their electric lighting provisional order.

Stone Asylum (Bucks).—The County Council have decided upon an electric light and power installation for the asylum at a cost of £4,700.

Hessle.—A committee has been appointed to consult with the Hull Corporation with a view to the introduction of the electric light to Hessle.

Removal.—The head offices of Messrs. Crompton and Co., Limited, will be removed on June 10 next to Salisbury House, London-wall, E.C.

Derby.—Two alternators have been sold for the sum of £150 by the Electric Lighting Committee. Mains have been ordered to be extended to Werburgh-street.

Stockton.—The Corporation have agreed to enter into further extensions of the electric works by the purchase of a new engine and dynamo at the price of £3,450.

Digitized by Google

Aberdeen Harbour.—At the last meeting of the Works Committee of the Harbour Board, it was agreed to obtain electric machinery for the bascule bridge at Regent Quay at a cost of £480.

Ilkley.—On the application of Mr. Alfred H Gibbings, of Cheapside, Bradford, the Board of Trade have granted to him a provisional order for the supply of electricity throughout the urban district of Ilkley.

Berkhampstead.—A special meeting of the Urban District Council will be held next month in order to discuss a resolution that the Council apply for a provisional order to supply electric light for the district.

Worksop.—The surveyor reported at Tuesday's meeting of the Urban District Council that progress was being made with the electric light works; the arc lamp standards had arrived, and would shortly be fixed in the streets.

Gloucester.—The advisability of adopting an electric motor for driving the laundry machinery at the new hospital at Over is under consideration. The Council have obtained sanction to borrow £9,425 for the purposes of electric lighting.

Colchester.—The Town Council have accorded to Messrs. Siemens Bros and Co, Limited, a vote of thanks for the efficient manner in which they had conducted the borough electric light works during the two years it was under their control.

New Branch.—Mr. G. W. Clarke, of Harold Wood and London, has recently opened a branch office and showrooms at 15, High-street, Grays, for the fitting-up of a large number of shops, etc., shortly to be connected to the new supply station.

Worcester.—The expenses of the deputation to the electricity works at Islington, Hammersmith, Brighton, Bradford, Southport, Blackpool, Bolton, Manchester, etc., came to £74. 16s. 6d. It is understood that the deputation comprised four members.

Little Lever.—The question of the supply of electric current in the township will be the subject of discussion at an interview between the General Purposes Committee of the Urban District Council and the Lancashire Electric Power Company shortly.

Norton.—The Board of Trade have granted to the Northern Counties Electricity Supply Company their provisional order for the manufacture and supply of electricity in Norton. The order includes all such portions of the town at present lighted by gas.

Torquay.—The high-tension main from Market-street being overloaded, it is proposed that a new high-tension feeder be laid from the town hall to Castle-circus at an estimated cost of £186. In Croft-road 130 yards of main are to be laid to supply Sorel with light.

Brighton.—Application is to be made for sanction to the borrowing by the Corporation of the sum of £663. 10s in order to defray the expense of purchasing two houses, required in connection with the erection of the buildings for the electricity generating (tramway extension) station.

Hartlepool.—The Guardians have decided to enquire into the advisability of lighting the workhouse by electricity. The present expenditure on gas is £400 a year, and it is thought that by a little outlay the boiler and engine at the workhouse could be used for generating electricity.

London-to Brussels Telephone. — The installation of the London Brussels telephone is now completed, and trials are at present in progress which will continue for the next month or six weeks. It is expected that the service will be placed at the disposition of the public about the middle of July.

Middlesbrough.—At last Wednesday's meeting of the Electric Lighting Committee it was reported that during the month of May £12 profit had been made by supplying electric light. The question of giving preference rates for lighting chapels and churches is being enquired into.

Horsham.—Sanction has been obtained to the borrowing of the sums of £13,700 for purposes of electric lighting and £300 for the purchase of land for depôt purposes, together with the Local Government Board's formal approval of the use of land belonging to the Council for the purpose of the electric lighting order.

Alfreton.—The Board of Trade have replied to the Urban District Council in answer to the Council's request for the reasons why the provisional order to enable the Council to light the town with electricity had been refused, stating that it was contrary to their regulations to give the information desired by the members.

City of London Electric Lighting Co.—We note the following particulars of the revenue of this Company for the past March quarter: sale for current, etc., £91,611. 12s. 7d.; working expenses, £45,728. 1s. 5d.—leaving available for interest on debenture stocks and loans, depreciation, special charges, and dividends, £43,883. 11s. 2d.

British Electric Works Co.—In the case of the petition of Messrs. Samuel Walker, Limited, for the compulsory winding-up of the British Electric Works Company, Limited, which had stood over for a month in order to enable a scheme of reconstruction to be perfected, adjournment for another month was granted on Wednesday.

York.—At the meeting of the City Council on Tuesday it was stated that as the result of the working of the electric lighting department for the past 12 months they had been able to pay their interest and sinking fund, and the whole of the preliminary expenses, amounting to something over £300. There was a small balance in hand in addition.

London Gazette.—The partnership between R. Lomax and H. Lomax, electrical engineers, 6A, Market-street, Darwen (trading as R. Lomax and Co.), has been dissolved by mutual consent.—The final meeting of the St. Helens and District Tramways Company, Limited (in liquidation), will be held on July 1 at Pearl Insurance-buildings, St. John's-lane, Liverpool.

Eastern Extension and Great Northern Telegraph Companies. A duplicate cable has been laid between Chefoo and Taku. This additional cable will lessen the risk of interruption of telegraphic communication with the North of China, and facilitate the transmission of trade exchanged with Taku and beyond.

Nelson.—The Town Council have approved the plans of the borough surveyor (Mr. B. Ball, A.M.I.C.E.) for the erection of an electricity generating station in connection with the refuse destructor at Reedyford, and have authorised application to be made to the Local Government Board for borrowing powers for £7,500 for that purpose. As the current will be required at the end of September, the work will be put in hand at once.

South Shields.—The half-yearly balance-sheet of the electric light works states the income for the half-year ending March 31 at £8 147. 18s. 3d., and the working expenses at £3,468. 9s. 11d., leaving a gross profit of £4,679. 8s. 4d. After paying interest on loans and contributions towards sinking fund there is a net profit of £2,802. 5s. 6d. From the commencement of the undertaking in 1896 there has been a net deficit of £3,435 12s. 3d. in the income.

Newcastle.—At a meeting of the Town Improvement Committee of the Corporation on Wednesday a report was received from Mr. Mordey, who had been called in by the Corporation to advise them with respect to a communication received from the Board of Trade, informing the Council that the Newcastle Electric Supply Company were going to endeavour to get powers to put down new cables in the streets with greatly increased voltage. It was decided to hold a special meeting on Friday to go fully into the matter.

Travellers' Colloquial German.—Mr. H. Swan, principal of the Central School of Foreign Languages, London, has come out with a third edition of his phonetic handbook for English-speaking travellers and students just at the time when members of the Institution will be able to find particular use for it. By its means pronounciation of jaw-breaking words is made easy, and the appendices for cyclists and photographers will be specially appreciated. The little book is published by Mr. David Nutt, 57-59, Long-acre, at the modest sum of 1s. 6d., which should prove an excellent investment.

Stock Exchange. — The Stock Exchange Committee have appointed June 19 a special settling day for British Electric Traction Company, Limited, further issue of 30,000 6 per cent. cumulative preference shares of £10 each (issued at £1 10s. premium), £7. 10s. paid (of which £6 is capital and £1. 10s. is premium), Nos. 160 001 to 190,000. The committee have also ordered to be quoted in the official list British Electric Traction Company, Limited, further issue of 2,074 ordinary shares of £10 each, fully paid, Nos. 120,001 to 122,074. The committee have further been asked to allow to be quoted in the official list Oxford Electric Company, Limited £50,000 4 per cent. debenture stock.

Paignton.—The Lighting Committee presented at the District Council meeting on Tuesday a report with reference to the scheme of electric lighting proposed to be carried out by Mr. Paris Singer at his own cost in the first instance, to be purchased by the town within 10 years. The committee stated they were unable to recommend further progress with the scheme but that the thanks of the Council be accorded to Mr. Singer for his kind offer. The Chairman explained that it was impossible for them to pledge the Council to purchase some years hence. He very much regretted that they could not avail themselves of Mr. Singer's offer. He was quite willing to carry out his part of the scheme, but they could not get powers. The report was adopted.

Post Office Telephones.—The Wandsworth County Court judge on the 4th inst. decided that the Post Office is not subject to the conditions proposed to be imposed by the Corporation of Richmond on the Post Office in laying wires in the streets of Richmond. The Corporation had demanded that if the positions of the cables had to be altered on account of street widening, the Post Office should pay for such alteration. We understand that the new system will be in operation at the beginning of September next in the City area, Westminster, and a portion of the Thames Valley extension. With reference to the statement that considerable orders for telephonic apparatus has been placed in America, the engineers' department state that the American orders have been mainly for switchboards, patented in America, and more suitable than English apparatus.

Salford.—The Electric Light Committee on Wednesday recommended that the "maximum demand" system of charging for current be abolished, and replaced by a uniform charge per unit of current consumed, 2d. per unit to be charged for power purposes and 4½d. per unit for lighting purposes; that a discount of 2½ per cent. be made on payment of accounts within one month of the demand note being delivered; and that in all cases where consumers had their own plant and used the Corporation's supply only when their own plant failed a maximum price of 8d. per unit be charged, with a minimum price of 13s. 4d. per quarter. The Chairman of the Committee (Mr. Alderman Shaw) said, according to the *Manchester Guardian* the "demand system" had caused a loss to the Corporation within the last three months of £1,900, and the loss would go on as long as the system was continued. The resolution was adopted, a course we regret to see taken, as other remedies might have been available. By abolishing the maximum demand system the committee run the risk of losing their best customers and to retain only the more casual users of the light.

Digitized by Google

Bournemouth.—Sanction has been received to a loan of £12,000 for public lighting. The lighting of Pokesdown and the purchase of the Bournemouth and Poole Electricity Company's undertaking are under consideration.

Chorley.—Sanction has been obtained by the Town Council to a loan of £21,300 for electric lighting purposes. The Town Council have resolved to interview the Lancashire Electric Power Company, and if possible obtain terms for a supply of electricity in bulk. The Local Government Board have also sanctioned a loan of £7,646 for a refuse destructor.

Glasgow.—Edward Paterson, dealer, Rodney-street, Glasgow, has been sentenced at Glasgow Sheriff Court to 15 months' imprisonment for receiving stolen electric cable, valued at about £90, the property of the electric lighting department of the Corporation. The prisoner declined to say from whom he got the material, and the thieves have not been discovered.

Islington.—A report from the Lighting Committee will come before the Council to-night recommending the laying of various lengths of distributing mains required in order to connect consumers who have already applied for a supply of electricity at an estimated cost of £612, as follows: Highbury-broadway, £235; Caledonian-road, £90; Anson-road, £121; Liverpool-road, £166.

Goole.—The Board of Trade have decided to grant a provisional order to the Urban District Council of Goole for the supply of electricity to the whole of the urban district of Goole, as constituted at the commencement of the order. The maximum price which the District Council may charge consumers is 11s. 8d. per quarter for any amount up to 20 units, and for each unit over 20 an additional 7d.

Wireless Telegraphy in the Navy.—Coastguardsmen who were signalmen of the higher standard are to be trained in wireless telegraphy at Portsmouth, so that they may take charge at the signal stations which have recently been fitted. It was intended by the Admiralty that the places should be held by naval signal ratings, but these are none too abundant, and the men cannot be spared from the ships.

St. Helens.—At the last meeting of the St. Helens Electric Supply and Tramways Committee it was decided to apply to the Local Government Board for sanction to the borrowing of £16,500 for the purpose of providing additional plant for electric lighting. At the same time instructions were given to apply to the Board of Trade for permission to borrow £10,000 for additional plant for electric traction purposes.

Cirencester.—At the last meeting of the Urban District Council the Lighting Committee presented a long and elaborate report on the question of supplying the town with electric light. They were of opinion that it was desirable to establish a system of electric lighting, and recommended that a provisional order be applied for in the next session of Parliament. The consideration of the report was adjourned to the next meeting.

Poplar.—The Borough Council have decided to petition the Home Secretary to furnish a return showing the number of deaths that have occurred to lead workers during the past three years. If no such return were available, the Home Secretary is to be asked to direct that a departmental enquiry be held upon the whole subject of the conditions of work in lead factories, and as to whether amended and improved regulations are necessary.

Chichester.—At Friday's meeting of the Town Council the Town Clerk read a report from a deputation who recently visited Windsor and inspected the electric lighting works there. The committee thought if works were constructed they should be in the hands of the Corporation. They contemplated a visit to inspect the works at Peterborough. It incidentally transpired that the members of the Council who went upon these visits paid their own expenses.

Fire at Charlton.—At the electrical engineering works of Messrs. Johnson and Phillips, Victoria Works, Charlton, an outbreak of fire occurred on Monday afternoon soon after 2 o'clock, resulting in a building of one floor 100ft. by 40ft. being partly burnt out, considerable damage being done to buildings, plant, and stock. We are informed that the fire will not cause any delay in execution of orders, as the firm are able to utilise other portions of their extensive premises to carry on the work.

Birkenhead.—The Borough Council propose to apply for sanction to the borrowing of £40,000 for the purpose of extending the electric lighting mains, providing generating plant for the south end of the borough, for the Rock Ferry district, and other places. Application is also to be made to the Board of Trade for a provisional order authorising the Corporation to supply electrical energy for public and private purposes within the districts of Higher and Lower Bebington and the district of Prenton.

Newcastle.—At the last meeting of the Newcastle Finance Committee of the Corporation, Mr. Laws, the city engineer, submitted plans for the erection of a lift from the street level to the municipal offices. Estimates are to be obtained from contractors, including local firms, with the view of the work being at once proceeded with. It was stated that the lift would be completed in four months, and if a supply of electricity could not be obtained from their own sources, arrangements could be made to obtain power to work it from one of the local companies.

Electric and General Investment Co.—We are informed that, subject to audit, the directors have decided to recommend the payment of the following dividends, etc., for the year ended May 31, 1901: a dividend of 5s. per share on the ordinary shares, of which 2s. per share was paid on account in December last, leaving 3s. per share to be distributed, and a bonus of 2s. per share, making together a present distribution of 5s. per share, or 25 per cent., or a total distribution of 7s. per share, or 35 per cent. for the year, and a dividend for the year ended May 31, 1901, of £50 per share on the founders' shares.

Personal.—We are informed that owing to rearrangement of the staff of the Edison and Swan Company, Mr. A. W. Hill will be severing his connection with the same after an uninterrupted period of 20 years, he having joined the staff of the American Edison Company before the formation of the English company, and was superintendent of the central station, Holborn-viaduct, with charge of the erection and maintenance of all the installations in London and district for the Edison and Swan Company. Mr. Hill has held the position of works foreman and engineer for the last 10½ years at the Ediswan Factory, Ponders End.

Lancaster.—The last report of the electricity department for the second half of the year shows that the price of current was increased ½d. per unit, both for lighting and motive power, in order to meet the additional cost of coal. The total net profits are £1,177. 9s. 3d., as compared with £670. 18s. for the previous year, disposed of as follows—viz.: to reserve fund, £750; to district fund, £427. 9s. 3d. The total for sale of current has increased from £3,876 4s. 8d. to £5,021. 19s. 11d., and for public lamps from £627. 12s. 9d. to £658. 8s. 11d., whilst the total expenditure has increased by £659. 12s. 4d., the increased cost of coal amounting for £395 13s 7d. of this amount. The reserve fund now amounts to £1 200. The total capital authorised and borrowed is £35,000, and the amount expended £35,380. 1s. 7d.

Cheltenham.—The Town Council have approved of an agreement with Mrs. A. F. Skarratt for the tenancy from year to year by the electric department, as electric supply offices and stores, of 335, High-street, at a rental of £80 per annum, with option of purchase at £1,750. At the meeting on Monday a letter from the Local Government Board was read, asking for further information as to an electric lighting loan of £6,000, and stating that the action of the Council in carrying out works in anticipation of loan sanctions was irregular. A reply was approved of giving the information required and calling the Board's attention to the fact that the application for sanction was made on Oct. 5 last, and the enquiry was not held until April 4, and unless the undertaking was to come to a standstill, it was practically impossible that works should not be carried out in anticipation of the Board's sanction.

Typeprinting Telegraph.—The Typewriting Telegraph Corporation, Limited, of Dashwood House, New Broad-street, E.C., have just issued an illustrated pamphlet descriptive of their typeprinting telegraph (Steljes's patent), by means of which any person is enabled to telegraph messages on either a telegraph or telephone line, which messages appear on the instrument at each end of the line similarly printed in Roman type on a paper ribbon. Amongst the advantages claimed for this system we note that batteries are not required, saving expense and trouble of maintenance. Very little practice is needed, and messages are automatically received during the absence of addressee, and privacy assured by locking the instrument case. There is no noise or publicity, as in telephoning, and the message being printed both by the sending and receiving instrument, ensures accuracy, fixes responsibility, and furnishes both parties with a record. Messages can be simultaneously sent to several receiving stations from one sending station. Printed and spoken messages can be transmitted simultaneously on the same telephone circuit. We are informed that the corporation will supply the apparatus by sale outright, with or without royalty, or on inclusive rental terms, and that instruments can be hired from H.M. Postmaster-General, and the National Telephone Company, Limited, who will contract for their maintenance.

Barnstaple.—Progress is being made with the electric lighting scheme. The report of Mr. Trentham has been considered in committee, and it is understood that it has given much satisfaction. It provides for the lighting of the whole of the town, with steam as the generating power. The Electric Lighting Committee intend to recommend the Town Council to use the extensive premises in Castle-street lately in the occupation of Mr. C. C. Cox for the purpose of an electric lighting station. Mr. Trentham considers that the water power at Raleigh is too small to be utilised, and recommends steam for the motive power. Public lighting is to be confined to streets where mains are laid for private lighting. In view of the narrowness of the streets, incandescent lighting could with advantage be adopted at Barnstaple. Mr. Trentham considers that 2,600 lamps of 16 c.p. would be soon taken up in the compulsory area, and the capital expenditure for this would be £16,225. If 5,400 lamps were provided for, a total expenditure of £21,450 would have to be incurred. A profit and loss account showed an estimated balance of £727, the charge to private consumers being placed at 6d. per unit. The Town Council have adopted the committee's scheme, and will apply to the Local Government Board for powers to borrow the money required. Mr. Trentham has been instructed to prepare the necessary plans and estimates in preparation for the enquiry.

New Issues.—The business of Messrs. Drake and Gorham has been formed into a limited liability company with a capital of £125,000. The vendors take £40,000 in shares and £66,000 in cash. The assets are certified at £40,000 and the stock at £12,541, and a further £10,500 for working capital is to be provided out of the issue of 85,000 £1 shares just being issued. The profits for the past five years are given as: in 1896, £10,166; 1897, £12,095; 1898, £11,411; 1899, £12,756; 1900, £12,349. The vendors, Messrs. Drake and Gorham, will continue to act as managing directors for seven years. The Uxbridge and District Electric Supply Com-

Digitized by Google

pany, Limited, who have a share capital of £20 000 divided into 4,000 ordinary shares of £5 each, of which 1,350 shares have been already issued, are issuing 2,650 ordinary shares of £5 each at par, for the purpose of working a provisional order under the Electric Lighting Acts, 1882-1888, granted and confirmed last session, under the title of the Uxbridge and District Electric Supply Order, 1900, to a syndicate, for the supply of electricity for lighting, and for all public private purposes within the area of supply, which consists of the township of Uxbridge and the parish of Hillingdon West, together comprising the Uxbridge urban district, and the parishes of Hillingdon East, Ickenham, Cowley, and Hayes, in the Uxbridge rural district, all in the county of Middlesex; and the parish of Denham, in the Eton rural district and the county of Buckingham.

Keighley.—At the meeting of the Town Council on Tuesday the committee reported that the Fleece Mills Company had, by advertisement in the papers, given public notice of their intention to apply for powers to carry on some business or businesses which in their opinion might conveniently or advantageously be combined with the business of the company, and that amongst such business were included the following—viz.: "To manufacture, provide, store, and sell gas and electric energy, etc.; to lay down mains, pipes, and cables, etc.; to hire out fittings, lamps, dynamos, and other requisites in connection with gas and electricity, etc.; to borrow or raise money for such purposes; and to apply for and promote, and obtain any license or order from the Board of Trade, or provisional order, or Act of Parliament to carry such objects into effect." The committee had instructed the town clerk to oppose such application, unless an undertaking was given by the Fleece Mills Company to the Corporation that such powers to be applied for were limited to the premises now owned by the company, and the committee asked the Council to confirm their action in the matter. Further conferences have taken place between the promoters of the Yorkshire Electric Power Bill and representatives of various non-county boroughs in the West Riding, including Keighley, with the result that satisfactory terms have been come to for the amendment of the Bill so as to meet the requirements of the boroughs, and the committee have, therefore, instructed the town clerk to withdraw the petition against the Bill.

Hampstead. — The Lighting Committee reported at the last meeting of the Borough Council that the delegates appointed by the committee had attended a conference with the London County Council and other metropolitan boroughs, at Spring-gardens, upon the question of the establishment of generating stations for the supply of electrical energy in bulk within the county of London, when the following resolutions were passed: (*a*) "That the conference regards it as essential to the interests of London as a whole that the present purchase clause of the Electric Lighting Acts which applies to defined areas should also be made to apply to such companies as propose to supply electrical energy in bulk to the whole of London without regard to area." (*b*) "That, while preserving intact the rights of the local authorities with regard to electric lighting and energy, in the opinion of this conference it is desirable that the London County Council should be in a position to undertake, if it so determine and if so requested by the local authority, the supply of electrical energy in bulk for the convenience of any districts desiring to be so supplied, provided that the Council does not become competitive with the local authority." "That these resolutions were passed with a view to the London County Council preparing a Bill on the subject, a copy to be sent to all municipal authorities interested for consideration before presentation." It was decided that enquiry be made of the Postmaster-General when the Government system of telephones will be at work in the borough, and that the parties complaining of inconvenience owing to the withdrawal of connection by the National Telephone Company be informed accordingly.

NEW COMPANIES.

The following new companies have been registered since our last issue:

Ossett and District Omnibus Company, Limited.—Capital, £500. Object: to work omnibuses and tramways by electric and other power.

J. Stenner and Co., Limited.—Capital, £15,000. Object: to acquire the business of Messrs. J. Stenner and Co., and to carry on the business of manufacturing and electrical engineers, etc.

T. C. Welding and Co., Limited.—Capital, £1,000. Object: to acquire and take over the business of Messrs. T. C. Welding and Co., of Liverpool, and to carry on the business of manufacturers of and dealers in electric fittings, etc.

Eagle Engineering and Motor Company, Limited.—Capital, £6,000. Object: to adopt an agreement between Messrs. R. Jackson and J. Kenworthy and J. B. Bindloss, jun. (for the company), and to carry on the business of engineers, electricians, wheelwrights, tubemakers, etc.

Millington, Everett, and Co., Limited. — Capital, £3,000. Object: to acquire from F. Millington the benefit of certain existing inventions, and to carry on the business of electricians, suppliers of electricity, manufacturers of and dealers in electrical, galvanic, and magnetic apparatus, etc.

Drake and Gorham, Limited.—Capital, £125,000. Object: to acquire the business of Messrs. B. M. Drake and J. M. Gorham at 66, Victoria-street, S.W., with the tenancy agreements of the premises where such business and its branches are carried on, and certain patents for use in the said business, etc.

Reading and District Motorcar Company, Limited.—Capital, £5,000. Object: to carry on in Reading, Berkshire, or elsewhere, the business of builders of and dealers in and with motorcars and other vehicles, carriers of goods and passengers, electricians, mechanical engineers, suppliers of motive power, traction, light, and heat, etc.

A. Reyrolle and Co., Limited.—Capital, £20,000. Object: to acquire the business carried on at 20, Pancras-street, Tottenham Court-road, London, as Reyrolle and Co., to adopt an agreement with A. C. Reyrolle, and to carry on the business of electricians, electrical and mechanical engineers, manufacturers of electrical appliances, etc.

PROVISIONAL PATENTS, 1901.

MAY 23.

10654. Improvements in resistances for the control of electric currents. Thomas Edgar Weaver, 159, Russell-street, Moss Side, Manchester.

10655. Improvements in or connected with electrolytic bells or apparatus. George Bell and George William Bell, 15, Water-street, Liverpool.

10686. An improved street lantern for gas and incandescent electric lighting. William Edgar, 23, Lower-mall, Hammersmith, London.

10687. Prepayment apparatus for the supply of gaseous, electric, or other fluids for a given period of time. Henry Cooney, 64, Carminia-road, Upper Tooting, London.

10730. Improvements in electric tram and railways. Robert Hacking, Augustus Wyvill Hancock and John Leighton, 24, Southampton-buildings, Chancery-lane, London.

10733. Improvements in high-potential electric switches. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (William Le Roy Emmet and Edward M. Hewlett, United States.) (Complete specification.)

10734. Improvements in train-control systems for electric railways. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (Frank E. Case, United States.) (Complete specification.)

10735. Improvements in electric circuit breakers. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (Samuel B. Stewart, jun., United States.) (Complete specification.)

10736. Improvements in high-potential electric switches. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (William Le Roy Emmet, Edward M. Hewlett, and Charles C. Badeau, United States.) (Complete specification.)

10737. Improvements in electric circuit breakers. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (Samuel B. Stewart, jun., United States.) (Complete specification.)

MAY 25.

10743. Improvements in electrical engines for surgical and dental purposes. Ernest William Mayer, 71, Great Portland-street, London.

10747. Improvements in electric ignition plugs for internal-explosion engines, and chiefly as used with motor road vehicles. Edward Gardner, Thomas Harry Gardner, and Lawrence Gardner, 55, Market-street, Manchester.

10756. Improvements in magnet coils or solenoids. Bernard Mervyn Drake, Charles Cornfield Garrard, Gilbert Scott Ram, and the Nernst Electric Light, Limited, 18, Southampton-buildings, Chancery-lane, London.

10757. Cut-out for incandescent lamps with glowers consisting of conductors of the second class. Charles Cornfield Garrard and the Nernst Electric Light, Limited, 18, Southampton-buildings, Chancery-lane, London.

10758. Improvements in electric incandescent lamps in which the glower or light-giving body is a conductor of the second class. Gilbert Scott Ram and the Nernst Electric Light, Limited, 18, Southampton-buildings, Chancery-lane, London.

10766. Improvements in electromagnetically-controlled looms and kindred textile machinery. Arthur Penrhyn Stanley Macquisten, 33, Renfield-street, Glasgow.

10769. Improvements in prepayment devices for telephones. Robert B. Jentzsch and Gebhard von Alvensleben, 33, Cannon-street, London.

10793. Improvements in electric indicators. William Joseph Polyblank, 4, Harley-street, Bow, London.

10795. Generating electricity for the propelling of machinery or for other similar and useful purpose. William Sunter, 8, Calton-hill, Edinburgh.

10848. Improvements in apparatus for winding coils for continuous-current dynamo and motor electric machines. Arthur William Tomkins, 62, Market-street, Manchester. (Complete specification.)

Digitized by Google

10869. Manufacture of incandescence bodies for electric lighting. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

10871. Improvements in telegraph and telephone systems. Frederick George Thomas Parsons and Douglas Hubert Sturman, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

10879. Improvements in voltaic cells. William Kennedy Laurie Dickson, 18, Southampton-buildings, Chancery-lane, London.

10887. Improvements relating to electric arc lamps. Hermann Otto Schmidt, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

10888. Improvements relating to electric switches. Friedrich Wilhelm Busch, 45, Southampton buildings, Chancery-lane, London.

MAY 28.

10903. Improvements relating to the electrolysis of salt. Eleanor Jane Plumber, Colinton, Midlothian.

10932. Improvements in wire cables. Ludwig Luckhardt, 100, Wellington-street, Glasgow. (Complete specification.)

10933. Improvements in joint and like boxes for electric cables. Albert Edgar Tanner and William Paul James Fawcus, 4, St. Ann's-square, Manchester. (Complete specification.)

10935. Improvements in domestic telephone plants for physicians and others. Albert Traub, 83, Alte Jacobstrasse, Berlin, Germany. (Complete specification.)

10951. Battery elements support. Charles Bernhardt Schoenmehl, 52, Chancery-lane, London. (Date applied for under Patents, etc., Act 1883, Sec. 103, Oct. 30 1900, being date of application in United States.) (Complete specification.)

10960. Circuit-closing device for the winding gear of electric clocks and the like. Max Möller, 321, High Holborn, London. (Complete specification.)

10961. Electric striking clock. Max Möller, 321, High Holborn, London. (Complete specification.)

10967. Improvements in stationary armatures and inductors. Victor Isidore Feeny, 60, Queen Victoria-street, London. (Allgemeine Elektricitäts Gesellschaft, Germany.) (Complete specification.)

10971. Improvements in and relating to controllers for electric railway and like vehicles. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Walter W. Tice, United States.)

10974. Improvements in and connected with electrodes for electrolytic cells. Philip Middleton Justice, 55, Chancery-lane, London. (Castner Electrolytic Alkali Company, United States.) (Complete specification.)

10975. Improvements in electrodes for electrolytic cells. Philip Middleton Justice, 55, Chancery-lane, London. (Castner Electrolytic Alkali Company, United States.) (Complete specification.)

10976. Improvements in electrolytic cells. Philip Middleton Justice, 55, Chancery-lane, London. (Castner Electrolytic Alkali Company, United States.) (Complete specification.)

10988. Improvements in telephone circuit systems. Ellis Freedom Frost, 111, Hatton-garden, London. (Complete specification.)

11000. Improved electric heating device. Emil Kastner, 111, Hatton-garden, London.

11003. Improvements relating to apparatus for transmitting and receiving electric signals. Georg Friedrich Rudolf Blochmann and Christian Emil Bichell, 45, Southampton-buildings, Chancery-lane, London.

11007. An improved combined electrical and mechanical motor. Andrew Benson and John Pugh Price, 18, Buckingham-street, Strand, London. (Complete specification.)

11013. Improvement in circuit-closing and interrupting devices. Franz Kuhlo, 37, Chancery lane, London.

MAY 29.

11034. Improvements in starting switches for electric motors. Thomas Edgar Weaver, 159, Russell-street, Moss Side, Manchester.

11050. Electric arc lamp. Edward Maurice Barnes, 31, Cannon-street, London.

11071. Improvements in electrical connections. John Gray, 16, Emperor's-gate, South Kensington, London.

11076. Improvements in and relating to means for extinguishing electric arcs applicable to lightning arresters, switches, and the like. Harry Lamm, 322, High Holborn, London. (Complete specification.)

MAY 30.

11112. Improvements in trolleys and junction frog-plates for use on electric railways and tramways. David Blythe Foster, Brotherhood Works, Leeds.

11120. Improvements in galleries or holders for gas, electric light, oil lamp, and the like globes or shades. Bertrand Frank Wyler, 1, Broad-street-buildings, Liverpool-street, London.

11134. Improvements in rail bonds for electric railways. Charles Burton Thwing and Charles Godfrid Wiborg, 15, Took's court, Cursitor-street, Chancery-lane, London. (Date applied for under Patents, etc., Act. 1883, Sec. 103, Nov. 10 1900, being date of application in United States.) (Complete specification.)

11135. Improvements in or relating to electric arc lamps. Samuel Henry Johnson, 111, Hatton-garden, London.

11168. Improvements in vehicles driven by electricity. Victor Isidore Feeny, 60 Queen Victoria street, London. (Allgemeine Elektricitäts-Gesellschaft, Germany.) (Complete specification.)

11172. Improvements in electricity meters. Martin Kallmann, 18, Southampton-buildings, Chancery-lane, London.

MAY 31.

11214. Improvements in wireless telegraphy. Harry Shoemaker, 111, Hatton garden, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Jan. 17, 1901, being date of application in United States.) (Complete specification.)

11237. Improvements in or relating to electric arc lamps. Societa Generale Italiana Edison di Elettricita 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc, Act, 1883, Sec. 103, Nov. 26, 1900, being date of application in Italy.)

11242. Improvements in electrical primers. Sir W. G. Armstrong, Whitworth, and Co., Limited, and George Stuart, 24, Southampton buildings, Chancery-lane, London.

JUNE 1.

11248 An improvement in the form of glass chimneys and globes for incandescent gas and electric lighting. George A. Lewes, 12, Evelyn mansions, Carlisle-place, London.

11253. Improvements in or connected with the application of electric motors to the driving of machine tools. The British Electric Plant Company, Limited, and Wilfred L. Spence, 19, Waterloo-street, Glasgow.

11254. Improvements in incandescent light fittings, more particularly applicable to electric incandescent lights. Clarence Metcalfe Stead, 30, Park row, Leeds.

11257. Improvements in and relating to electrolytic incandescence lamps. John Robert Quain and Thomas Thomson Turnbull, 9, Warwick-court, Gray's-inn, London.

11277. An improved apparatus for utilising electric lamps in the heating of plates and other domestic utensils and in the boiling of water and other liquids. Richard Wade Boyd, 11, Southampton buildings, Chancery-lane, London. (Complete specification.)

11280. Improvements in electrical reversing switches and in mechanism for operating them. Coloman de Kandó, Birkbeck Bank-chambers, Southampton buildings, Chancery-lane, London. (Complete specification.)

11290. Improvements in electric contact makers and breakers. The Pick Motor Company, Limited, and John Henry Pick, 4, South-street, Finsbury, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on June 22.

1900.

7691. Electrical work measuring instruments. Johnson. (Hartman and Braun.)

10065. Automatic magnetic circuit breakers. Lake. (Scott.)

10974. Electric brakes for railway cars and the like. Newell.

10172. Apparatus for starting and controlling electric motors. Preece.

11011. Electrical switches and cut-outs for heavy currents and high potentials. Clothier.

11677. Parallel running of alternate-current machinery. Leake.

13515. Overhead trolley wires or conductors for electric traction, overhead electric cables, or the like. Hacking.

13573. Apparatus for electrically lighting railway trains. Parker.

13639. Electric meter. Bloxham. (Soc. Ch. Mildé, Fils, et Cie.)

13865. Insulating supports for electrical conductors. Wright and Aalborg. (Date applied for under International Convention, Jan. 2, 1900.)

13999. Arc lamps. Bénard.

14069. Lightning arresters. Wise. (Actiengesellschaft Elektricitätswerke, vorm. O. L. Kummer und Co.).

1901.

181. Electric light switches. Lundberg and Lundberg.

2394. Distributing electricity and apparatus for use therein. Ransford. (Soc. Anon. des Brevets Dolter.)

5026. Machine or apparatus for measuring the lengths of electric cables or wires, ropes, and the like. Claremont and Hyde.

Digitized by Google

5098. Multiple-conductor cable terminal or analogous fittings. Nisbett.

3513. Electric meters. Vittorio Alessandro Arcioni.

3964. Means for use in operating from a car or train switches employed with a surface-contact system of electric traction. Parker.

THE RIVAL WEST OF SCOTLAND POWER SCHEMES.

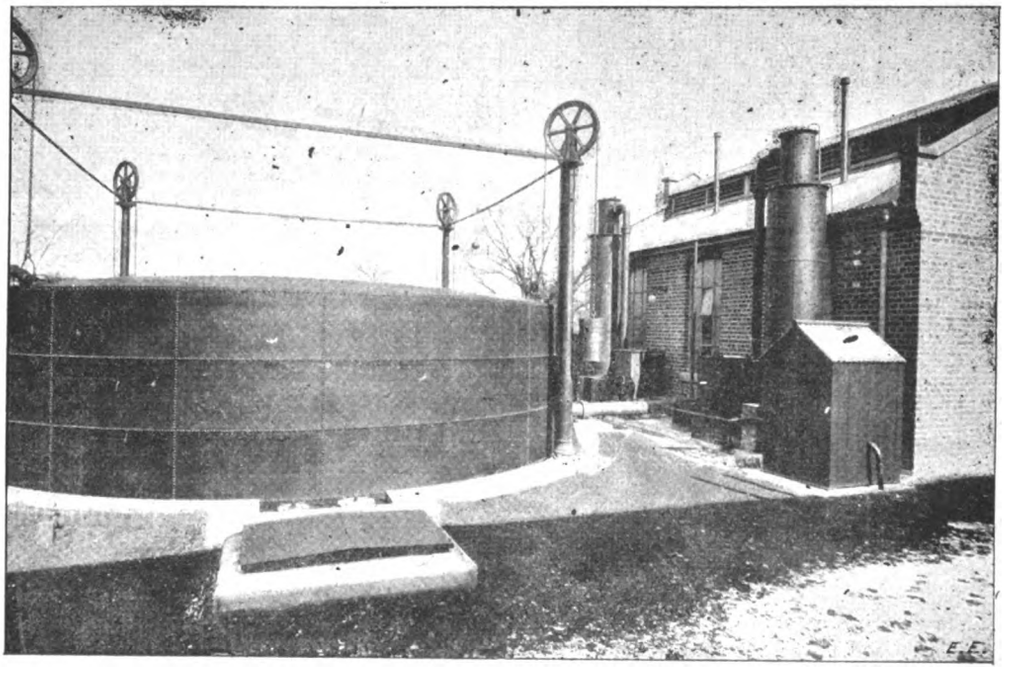
The parliamentary enquiry into the rival schemes promoted by the Caledonian Electric Power Company and the Clyde Valley Electric Power Company respectively for supplying electrical energy to a large area of the West of Scotland around Glasgow has resulted in a victory for the Clyde Valley Company. The proceedings before the Select Committee of the House of Commons presided over by Sir James Woodhouse lasted for more than three weeks, and in the end the chairman declared the decision of the committee to be in favour of the Clyde Valley Bill. Among the petitioning bodies against both schemes were Port Glasgow, Motherwell, Paisley, Partick, Greenock, Kilmarnock, Ayr, Hamilton, Govan, Airdrie, Coatbridge, Kinning Park, and others. Reduced to simple terms, the case for these burghs was that they wanted to reserve their rights to provide electrical energy within their own areas for their own people. The scheme which the Select Committee have passed is by a long way the smaller of the two, but the decision in favour of the Clyde Valley Bill must be taken as representing the balance of testimony of the manufacturers and technical witnesses. The area over which the Caledonian Bill proposed to supply comprises no less than 1,135 square miles—practically the whole of Ayrshire and Lanarkshire—whereas the area included in the Clyde Valley scheme is 732 square miles. At the present time a supply of electricity is only being given in 13 square miles out of 710, excluding Glasgow. Large iron and steel works are situate in this area and a great many coal-pits. Altogether, there are some 1,200 works of importance which will come within the range of supply. In regard to the system of supply, all calculations have been based on the adoption of the multiphase alternating-current system, which is largely used in America and the Continent. In the event of a local authority taking a supply in bulk for lighting and also for power, it is thought that it will be possible to give a supply for power by an alternating current, and for lighting a separate supply transformed into continuous current. It is proposed to erect the three generating stations provided for under the Bill in the parishes of Dalzell, Renfrew, and Paisley respectively, and to place them so as to be coupled up for the purpose of an interchange of factors, and also so that they may supplement each other and be mutually supporting in the case of any failure of the plant. The capital of the company will be £900,000, with £300,000 borrowing powers, or £1,200,000 in all. Provision has been made in the estimates for two stations of 10,000 kw., and one of 5,000 kw., with a voltage of 10,000. The estimates of cost include £75,000 for connecting the stations, and £105,000 for transformers, which brings the total initial cost of distribution plant, etc., up to £400,000. One argument which seemed to influence the committee very considerably in deciding in favour of the Clyde Valley scheme, was that it is promoted by the largest industrial consumers in the district. They include Lord Hamilton of Dalzell, Sir Wm. Pearce, Bart., Sir Mitchell Thomson, Bart., Sir Chas. Cayzer, Sir David Richmond, and others. These gentlemen, it is said, do not look so much to profit out of the company as to a supply of electrical power, which will certainly tend to develop all kinds of manufacturing

Map of the Areas included in the Clyde Valley and the Caledonian Power Bills. The black contour shows the area of the Clyde Valley Scheme, while the shaded spots numbered 1, 2, and 3 denote the proposed sites for the generating stations. The area proposed under the Caledonian Bill is included in the shaded contour, and the thick black spots show where it was proposed to erect the seven generating stations.

Digitized by Google

industries in the area, and to help the establishment of tramways for the greater convenience of the working classes. We have reason to believe, however, that the committee were influenced more by the fact that the Clyde Valley Bill is the less ambitious scheme of the two, and that while the proposed area is only 732 square miles, as compared with 1,135 square miles under the Caledonian Bill, it really embraces the whole of the important manufacturing and mining districts around Glasgow. Again, the Caledonian scheme provided for no less than seven different generating stations as against three under the other scheme. At present the use of electrical power in coalmines is very limited, but a supply of power on a large scale and at the cheapest possible rates—3d. per unit for the first 400 hours and 2d. per unit for any further quantity are the maximum charges under the Bill—will do much to forward the application of electricity to underground haulage. The engineer to the Clyde Valley scheme is Mr. Robert Robertson, of Glasgow, and in the course of his evidence before the Select Committee he referred to the danger from motor-generators in fiery coalmines. He agreed that there was risk from sparks in such mines. Such a risk would make it quite impossible, in his opinion, to put in anything in the way of an electric continuous-current motor. Under the system of distribution proposed by the Clyde Valley Company, the motors would be on the alternating-current system, the use of which in mines gave rise to little danger owing to the fact that there was practically no liability to spark. Before being allowed to proceed, the Clyde Valley Bill was severely handled as regards clauses. The city of Glasgow is expressly excluded from the scheme, and provision is made for the protection of the Corporation against any damage which may result either from electrolytic action or from the carrying out of the works under the Bill. In addition to the general provision for the protection of "authorised distributors," including local authorities to whom provisional orders have been granted, there now appear special clauses for the protection of the burghs of Govan, Partick, Port Glasgow, Paisley, and Hamilton. In respect of the first three places, the company are prohibited from exercising any of the powers under the Bill except with the consent of the local authorities, while in regard to Paisley and Hamilton they are permitted to lay mains through these burghs to any other place within the area of supply. With regard to the position of burghs which in the future may become authorised distributors, the amended Bill places them in the same position as burghs already authorised. Special provisions are also inserted for the protection of the Trustees of the Clyde Navigation, railway companies, the Hamilton, Motherwell, and Wishaw Tramways Company, and the Scottish House-to-House Electricity Supply Company. When declaring the preamble of the Clyde Valley Bill proved the chairman explained that the intention of the committee was that the supply of power should be of such undoubted magnitude that the use of it for lighting purposes should be subordinate to that of the ordinary power. On the proceedings for the adjustment of clauses a clause by the promoters, suggesting that subscribers might be allowed to use 25 per cent. of the power taken for motive purposes for lighting, was objected to on the ground that 5 per cent. was quite sufficient. The chairman took the view that this was a very important matter, as it had come up for the first time, and the decision of the committee might form a precedent. Eventually the following clause was agreed to: "Provided that where energy is supplied to any person for power within the area of supply of any authorised distributors the energy used by such person for such lighting purposes shall not in any year, except with the consent in writing of the authorised distributors, exceed 20 per cent. of the total amount of energy supplied to such person, and save as aforesaid the company shall not supply energy for lighting purposes."

The engineer to the unsuccessful Caledonian Bill was Mr. A. A. Campbell Swinton, of Victoria-street, S.W.



Gasholder and Producer House, Isolation Hospital, Walthamstow.

The Clyde Valley Bill, as amended, stands reported for third reading.

THE ENGINEERING EQUIPMENT OF THE NEW ISOLATION HOSPITAL, WALTHAMSTOW.

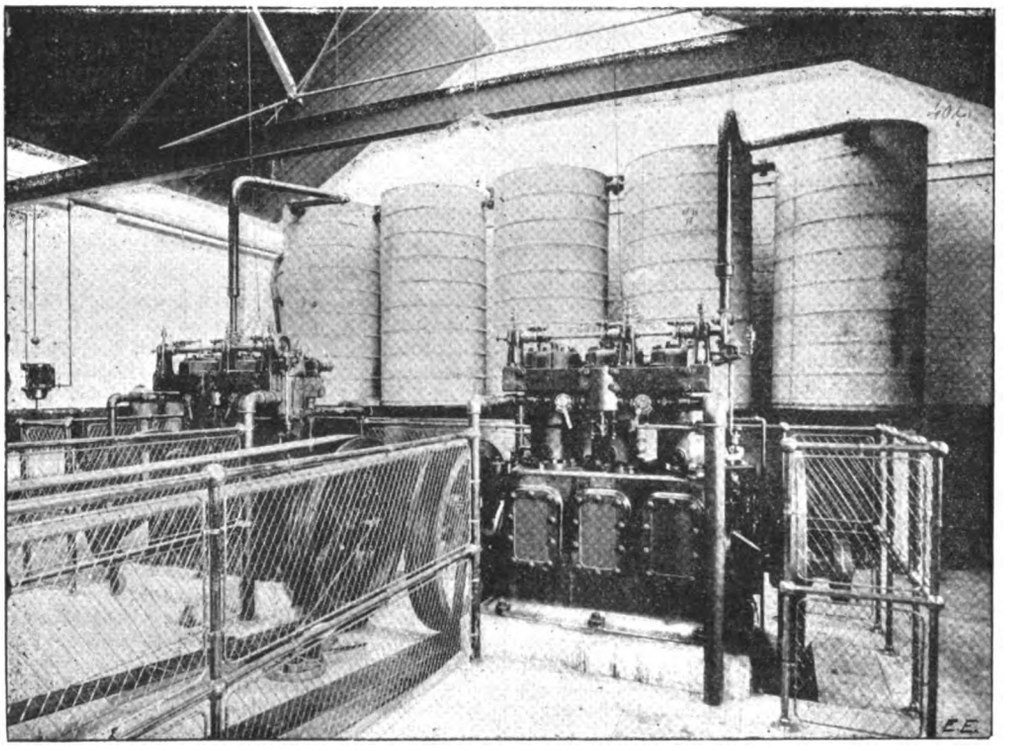
We are indebted to the British Westinghouse Electric and Manufacturing Company, Limited, for the following description and photographs:

The new isolation hospital of the town of Walthamstow has just recently been completed. It is built throughout on the most modern lines, and there are many points of interest and novelty in the engineering equipments. In 1894 the District Council acquired some 20 acres of land at Chingford, near Epping Forest, of which 5½ acres has been enclosed for the grounds and site of the new hospital and its future extensions. The population of Walthamstow is over 100,000, and considering that the buildings at present erected are capable of accommodating only 46 patients, while the usual provision is at the rate of one bed per 1,000 inhabitants, it is probable that extensions will be carried out very shortly.

The hospital buildings are seven in number, comprising four pavilions for the patients, the administrative building, the engineering building, and a porter's lodge. Of the

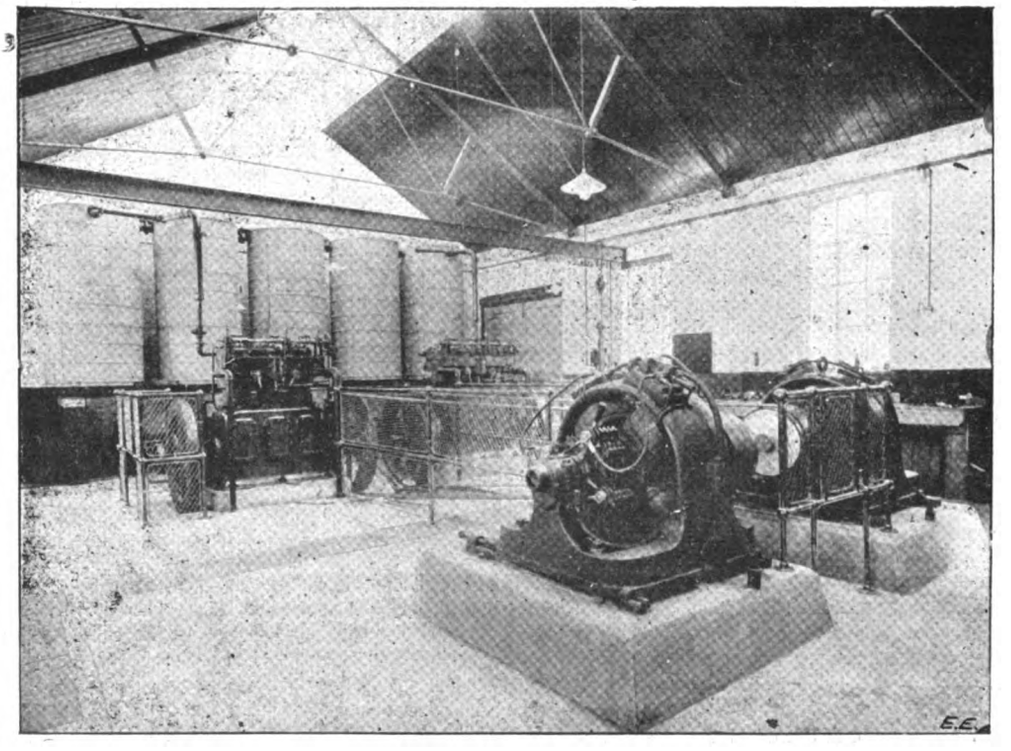
Digitized by Google

four pavilions, three contain 14 beds each, and the other one four beds. The interior walls are finished with Keen's cement, and all corners are rounded. The floors, partitions, etc., are of polished teak. They are one storey high, the three larger pavilions being divided by an intermediate



28-h.p. Westinghouse Gas-Engines, Isolation Hospital, Walthamstow.

nurses' duty-room into two wards of six beds and eight beds respectively. The cubic space per bed is 2,009 cubic feet, and the floor area per bed is 154 square feet. The wards are heated by a Manchester firegrate in the centre and by an open fireplace at one end. Warmed air is



Westinghouse Generators, Isolation Hospital, Walthamstow.

admitted to the wards by inlet pipes under each bed, the outlet being by valves set high up on the walls. All the buildings are of red brick, with roofs of board, felt, and slate. The administrative building is of similar materials and style to the others. It is for the accommodation of the resident medical officer, matron, nurses, and the general domestic staff, and is two storeys high, containing separate apartments for the staff, large dining-rooms, kitchens, etc.

The engineering plant of the hospital is of exceptional interest. In a separate building are located gas producers, electric plant, laundry, and disinfecting machinery. The gas and electricity plants are in duplicate. Two Dowson gas generators are installed, each capable of producing 1,000 cubic feet of gas per hour. Each producer has its full complement of additional plant, including vertical steam-boiler fitted with superheater, injector, and the usual fitting; a condenser, a hydraulic box, a coke scrubber, and a sawdust scrubber. The gasholder is 24ft. in diameter by 10ft. deep, fitted with an inlet pipe 8in. in diameter, and with two outlet pipes of 5in. and 4in. diameters respectively. The fuel used is anthracite, and the total cost of producing the gas is about 7d. per 1,000 cubic feet.

Digitized by Google

The gas supply is utilised for all power, heating, and lighting purposes through the hospital buildings. Two Westinghouse gas-engines are operated by the producer gas, being fed from the 4in. main. These engines are of the well-known three-cylinder type. Since their introduction a few years ago Westinghouse gas-engines have quite revolutionised gas-engine practice, and competed successfully against the best of steam-engine practice. They are equal to the best of steam-engines even on such points as noiseless running, even rate of rotation, automatic speed regulation with widely varying loads, self-starting, and economy in operation. Westinghouse gas-engines are built in stock sizes up to 650 h.p. units, but they are in use in sizes of over 1,000 h.p. each. The two installed at the Walthamstow Hospital are of 28 h.p. each, and are used for driving electric generators supplying current for the electric lighting of the hospital buildings, throughout which there are in all about 350 incandescent lamps installed. Two dynamos are installed, each belt-driven by a gas-engine. A storage battery of 55 cells is placed across the supply mains. The generators are compound wound, but when the battery is in circuit the machine series windings are cut out. The electric mains between the generators and the hospital buildings are of lead-covered cables drawn into iron pipes in the ground, and the mains are all duplicated, so that risks of total or lengthy interruptions to the supply are reduced to a minimum. The buildings are wired on the steel tube conduit system, and the circuits are taken from distribution switchboards, no one circuit having more than eight 16-c.p. lamps on it.

The laundry and disinfecting arrangements are on the most modern and improved principles. A hydro-extractor, two washing machines, two mangles, an ironer, a blower for the drying chamber, and a ventilating fan are all operated by a 6-b.p. electric motor, which drives an overhead shaft, to which the machines are coupled by belts. The disinfecting chamber in connection with the laundry is divided into two parts, and a Washington Lyons disinfector is built in the dividing wall. The infected clothing is received at one side, placed in the disinfector, where it is subjected for some time to steam at a pressure of 22lb. per square inch, and then dried by a current of hot air, and withdrawn at the other side.

The gas supply drawn from the gasholder 5in. outlet pipe is distributed throughout the buildings for heating, cooking, and gas-lighting purposes. There are four gas-heated water-boilers, each capable of heating a circulating tank of 80 gallons capacity; also a boiler for heating a 50-gallon tank for scullery purposes. These hot-water supplies are used for baths, lavatories, and general domestic purposes. The cooking apparatus consists of a large gas oven 4ft. 8in. by 2ft. 9in. by 2ft. deep, a cooking range of three ovens 17in. by 17in. by 27½in. deep, hot-plates, carving tables, cupboards, etc., all heated by gas. The gas supply to the lighting, cooking, and heating apparatus is carburetted to give a decided and unmistakable odour for the detection of leakages.

The total cost of the buildings and their equipments, which are now practically complete, will work out to be about £30,000. Walthamstow is a town which embraces a large area, and its population is increasing at a very rapid rate. It would hardly do to express the hope that the District Council's new hospital may be brought into very great use, but it is certain that no more convenient or better place could be provided for those unfortunate ones who are compelled to avail themselves of its advantages.

ON TESTROOM METHODS OF ALTERNATE-CURRENT MEASUREMENT.*

BY ALBERT CAMPBELL, B.A.

The object of this paper is to describe a number of methods of measurement, some of which are capable of fairly general application, while others are only of use in special cases. Many of these methods are novel, I believe, and most of the others are not well known. Owing to the nature of the subject it is not possible to connect the whole into a coherent sequence, but for convenience of reference I have numbered the methods consecutively.

* Paper read before the Institution of Electrical Engineers.

SECTION A.—TRANSFORMER METHODS OF MEASURING CURRENT, VOLTAGE, AND POWER.

In the testroom there is no special difficulty in measuring either currents or voltages of ordinary magnitudes; with continuous currents the use of moving-coil instruments renders the measurement of very large or very small values easy and accurate. With alternating currents, however, the measurement of the extreme values is not so easy, and it is for this purpose that transformer methods are specially valuable. Fig. 1 shows

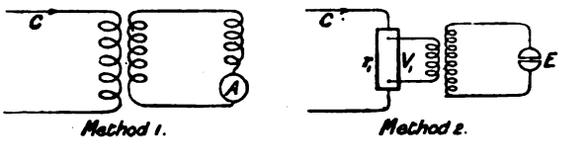


FIG. 1.

two typical methods. In the first method (which is fairly well known), C, the whole current to be measured, goes through the primary coil of a transformer, the secondary of which is connected to an ammeter, A. In Method 2 the current passes through a low non-inductive resistance, r_1, giving a small voltage drop, V_1, which is transformed up so as to give readings on the electrostatic voltmeter, E. As to Method 1, some years ago I investigated the conditions by which the ratio of current transformation can be kept sufficiently constant and independent of frequency. I found that it was necessary to have: (*a*) an air-core transformer, or one with a well-closed iron circuit; (*b*) relatively low resistance and high inductance in the secondary circuit.

Method 2.—It is to Method 2, however, that I wish to draw special attention at present. Here the measuring instrument, being electrostatic, is unaffected by variations in frequency, and if of good type has a very high degree of accuracy. [If a reflecting electrostatic voltmeter be set up in a fixed position, and a scale for it (say, at 2m. distance) be drawn by calibration with a potentiometer and direct current, an accuracy of at least 2 in 1,000 is attainable over a large part of the range. In most of the measurements in this part of the paper I have used such a voltmeter.] For currents from five amperes and upwards, the resistance, r_1, should be so small that not more than 0·5 or at most one volt is lost in it. If the voltmeter reads to about 120 volts, this necessitates a high transformation ratio—at least, 1 : 100 in the transformer. To keep the voltmeter readings proportional to the current, I find it best to use a transformer with (*a*) a well-closed iron circuit; (*b*) a highly inductive primary coil of very low resistance—*i.e.*, large time constant.

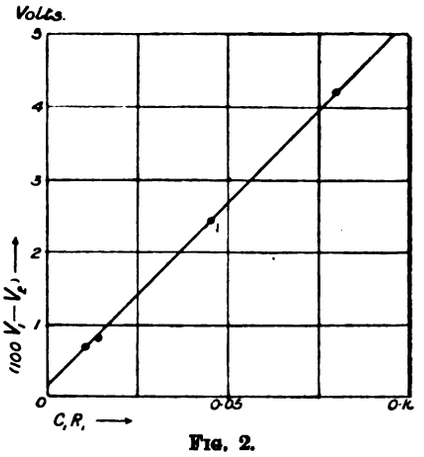

FIG. 2.

It is difficult to thoroughly carry out condition (*b*) without employing a considerable weight of either iron or copper, but very fair accuracy may be attained with a quite small transformer, as the following instance will show: The core consisted of annular iron stampings of total weight about 1·5 kilos; the primary coil had 100 turns of No. 16 wire, the secondary 10,000 turns of No. 40; r_1 had a resistance of one ohm and the resistance of the primary coil was 0·107 ohm. The divergencies of the observed ratio, $V_2 : C_1$, from the value 10 are shown in Table I.

TABLE I.

Frequency. ⌒ per second.	Error in ratio, per cent.
39	−1·9
86	−0·8

The primary current at one volt (86 ⌒ per second) was 0·17 ampere. By inserting known resistances in the primary circuit the curve in Fig. 2 was obtained, and thus it was proved that these divergencies are (practically) entirely due to the ohmic drop of volts in the primary. If such a

Digitized by Google

transformer is to be used on a circuit of nearly constant frequency, the ratio of the windings can be altered slightly so as to give an error almost negligible, or a few extra ends may be brought out to suit various frequencies. Perhaps an easier plan is to have a small range of adjustment on one of the parallel wires forming the low resistance, r_1. It is possible, however, to compensate for changes of frequency by Method 2*a*, shown in Fig. 3. Here the total current, C, after passing through the small resistance, r_1, passes through a turn or two on a very small compensating transformer, *t*, whose secondary is connected (reversed) in series with the secondary of T and the voltmeter. As the frequency is raised the

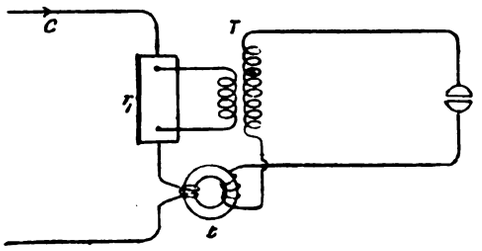

FIG. 3

transformer, *t*, subtracts more and more from the voltmeter reading, and thus compensation can be secured. The advantages of Method 2 are that with one voltmeter and a set of low resistances a very wide range of currents can be measured; also no disturbing inductance is introduced into the main circuit. It will be noticed that a transformer of high ratio like that described above gives a means of measuring small voltages with very small expenditure of current, but it is mainly to its use in conjunction with a low resistance that I would draw attention.

Measurement of Power.—For the measurement of power (or energy) transformers are often of great assistance, and in several well-known types of watt-hour meter they are employed with success. Under this head I shall content myself with mentioning two methods (3 and 4) shown in Fig. 4, the first due to Mr. M. B. Field, and the second published recently by myself. In

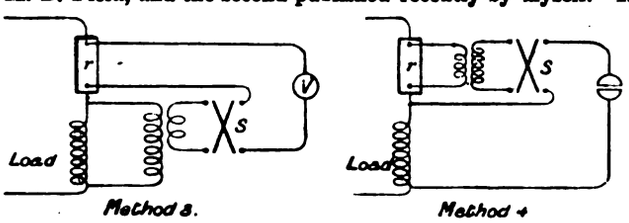

FIG. 4.

both of these a small resistance, *r*, is placed in series with the load, and S is a reversing switch. In Method 3 the voltage on the load is transformed down and added and subtracted from that on *r*, giving resultants P and Q, measured on a hot-wire voltmeter. In Method 4 the voltage drop on *r* is transformed up and the resultants P and Q (similarly obtained) are measured on an electrostatic voltmeter. For both methods

$$\text{Watts} = \frac{P^2 - Q^2}{4\,m\,r},$$

where *m* is the ratio of the transformer.

Method 4 can be used with fair accuracy to measure power with power factors down to 0·1, or even lower. For this the resistance of the primary of the transformer must be made very small, so that the secondary voltage may be almost exactly in opposite power phase to the primary potential difference. (The

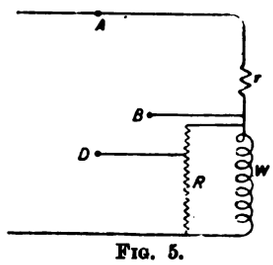

FIG. 5.

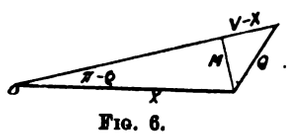

FIG. 6.

small angular deficiency may be measured by Method 6 below.) For example, with 50 volts on the load and 50 volts from the transformer, a power factor of 0·1 would give $P - Q \doteqdot$ seven volts—*i.e.*, the error of reading could be below 2 per cent. even on a voltmeter reading to 100 volts.

Method 5.—The three-voltmeter method as usually employed has several disadvantages; these are mainly due to the fact that, in order to get good readings, the auxiliary resistance must use up a considerable fraction of the total available voltage, and, what may be worse, tends to alter the wave-forms in the circuit. In the two-voltmeter methods (3 and 4) this is avoided; there is, however, a simpler modification of the three-voltmeter method which also gets over the difficulty. This is shown in Fig. 5, where *r* is a relatively small resistance, and R a very high resistance in parallel with the load, W. A convenient fraction $\left(\frac{1}{n}\text{th}\right)$ is picked off R by B D, and the three-voltmeter method is applied to A, B, and D. The result multiplied by *n* gives the power taken by W. In another modification the resistance, R, is put across both *r* and W, but a more complicated formula is then required.

Method 6.—*Measurement of Power Phase Differences close to* 180*deg.*—Let the effective voltages be V and X. (1) Let V be nearly equal to X, and let the small difference V − X be measured by an electrostatic voltmeter and a quick change-over key. Then Q, the small effective resultant of V and X, is found either by a low-reading voltmeter or by the help of a phase turner, or a transformer of high ratio, and an ordinary range electrostatic voltmeter. Then, as will be seen from Fig. 6,

$$\text{Sin}\,\phi \doteqdot \frac{M}{X} = \frac{\sqrt{Q^2 - (V-X)^2}}{X}$$

(2) If V is not nearly equal to X, let a high resistance be put across the greater (say V) and V^1 a fraction of it picked off as nearly as possible equal X. V^1 and X are then combined as in (1). [The transformer must not be used here for measuring Q.] I have found the above method useful for measuring approximately the power lag between the primary and secondary (open) potential differences in transformers. In one case, for example, the lag was found to be (180deg. − 0·15deg.). Similarly, the lag between two independent voltages very nearly in phase may be measured by reversing one of them and proceeding as above.

SECTION B.—THE TESTING OF WATT-HOUR METERS.

I. *Real Non-Inductive Loads.*—When sufficient power is available (at the proper frequency), the tests are usually easy, the chief difficulty sometimes being to find the gearing ratio between the quickest moving part and the dials, for some of the makers cannot be persuaded to mark this clearly on the meter. When the loads are above 2 kw. or 3 kw.,

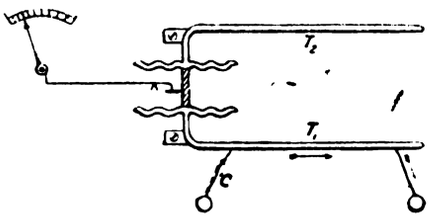

FIG. 7.

special non-inductive resistances are desirable in addition to lamps. I have found that a very convenient and cheap type of resistance frame for this purpose consists of strips of copper nickel each 1cm. broad, 1m. long, and capable of carrying 50 amperes. As the strips sag with the heat developed they are pulled taut by light springs which pull at the middle points of the strips. With such frames a steady non-inductive load is easily obtained. Some meters are so much affected by inductance in the load that the introduction even of a small Kelvin balance (to measure the current) is undesirable. The want of a non-inductive ammeter in this and other cases led me, seven or eight years ago, to devise and make a thermal ammeter which, although I exhibit it now only as a curiosity, has some points of interest about it. It consists (Fig. 7) of a form of differential air thermometer in which the bulbs are replaced at each side by thin-walled metal tubes, T_1 and T_2, of small diameter (1mm. to 2mm). Each of these is connected with a small aneroid chamber of extremely small internal volume. These chambers act against one another, and their differential action is magnified by ordinary aneroid mechanism, as shown in the figure. The current to be measured is passed along the tube T_1 (or a set of tubes electrically in parallel), while tube T_2 in the same enclosure acts as a compensator. The use of the thin hot tube acting as its own air chamber is to give the maximum quickness in attaining steady readings. To compensate for the decrease in the expansibility of the air as the temperature rises, the hot tube was made of a material having a considerable resistance temperature coefficient. Such a hot-tube ammeter, though non-inductive, dead-beat, and low in resistance, was scarcely accurate enough for careful testing work, but I think the principle is worth recording here.

II. *Inductive Loads.*—As several types of energy meter suitable for measuring inductive loads are now in common use, it is often necessary to test with inductive loads going down to power factors of 0·6 to 0·7. To use an ordinary wattmeter as standard is objectionable, as its errors may be as large as those of the watt-hour meter under test. I have used

Digitized by Google

the following method (7) for some years past and have found it convenient and accurate.

Method 7.—This is shown in Fig. 8, in which M is the watt-hour meter under test. The load consists of a non-inductive resistance, L, in series (through mercury pools) with an inductive part consisting of a Kelvin balance and a set of copper coils (N) wound inductively. In order to be able to make sudden measurements of the resistance of this inductive portion, mercury-cups are so arranged that it can be quickly switched

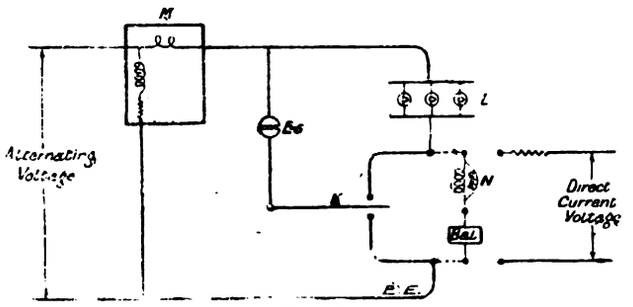

FIG. 8.

over into connection with a direct-current circuit and the resistance measured by reading current and potential difference on a Weston instrument. While the meter is running, the current, C, is read on the balance, and by the help of the switch, K, the voltage, V on L, and the total voltage, U, are read on the electrostatic voltmeter, Es. If r = mean resistance of the inductive part, then

$$\text{power} = C\,V + C^2\,r,$$

and

$$\text{power factor} = \frac{W}{C\,U}.$$

In practice r is made as small as possible, so that a small error in $C^2 r$ has a very small effect upon the value of W, while the C V part can be measured with extreme accuracy. The coils which make up N must have no iron near them, eddy currents must be avoided, and mutual induction must be

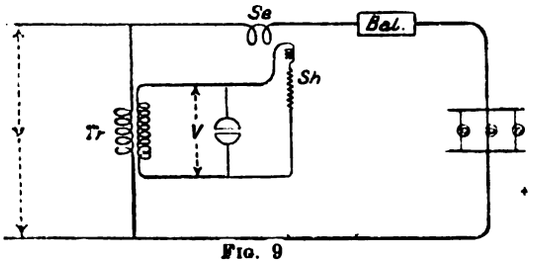

FIG. 9

guarded against except where two of the coils are identical in winding, in which case their impedance in parallel can be conveniently varied by varying their relative positions. The method is also suitable for testing wattmeters.

Method 8.—I have sometimes found it convenient to use a somewhat different method by which the measurement of resistance is rendered unnecessary. This consists simply in measuring w, the power in the highly inductive part, by the three-voltmeter method (or by an ordinary wattmeter), the total power being C V + w. Since w can be made to be only a small part of the whole power, this is accurate enough, and the coils, N, may here have iron cores.

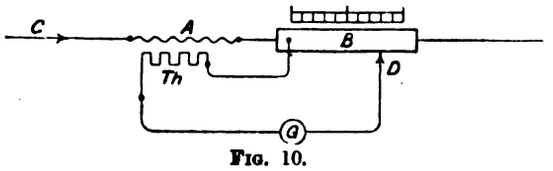

FIG. 10.

III. *Fictitious Loads.*—Unfortunately it very often happens that sufficient power (at the proper frequency) is not available to allow the meter to be tested with the actual loads at which it is to be used. It thus becomes necessary to arrange fictitious loads whose action on the watt-hour meter shall be practically identical with that of the corresponding real loads.

Method 9.—When the source of supply can furnish the current, but not at a voltage quite high enough for the load required, the well-known arrangement shown in Fig. 9 may be used. The shunt coil, Sh, is disconnected from the series coil, Se, and is connected with a transformer, Tr, which raises the supply voltage, v, to a suitable value V. The voltage v must be high enough to allow the series circuit (series coil, balance, and lamps) to be practically non-inductive.

Method 10.—When a large current is required, a method which I have published recently will be found useful. In it the large current obtained at a low voltage passes through the Kelvin balance, the series coil of the meter, and a low non-inductive resistance. A transformer of high ratio, with its primary across this low resistance, furnishes from its secondary the volts for the shunt circuit.

SECTION C.—THERMOPILE METHODS.

A well-known but little used way of measuring a current consists in passing the current through a conductor near which are one set of junctions of a thermopile. With rightly chosen conditions, the deflections of the galvanometer connected with the pile are practically proportional to the square of the effective value of the current. In common with many other thermal methods, the action is dead-beat, but there is usually the accompanying disadvantage of sluggishness, the zero point not being regained instantly on switching off the current. By making the hot wire and the junctions extremely small, this sluggishness can be much reduced. I have tried a thermopile of iron and

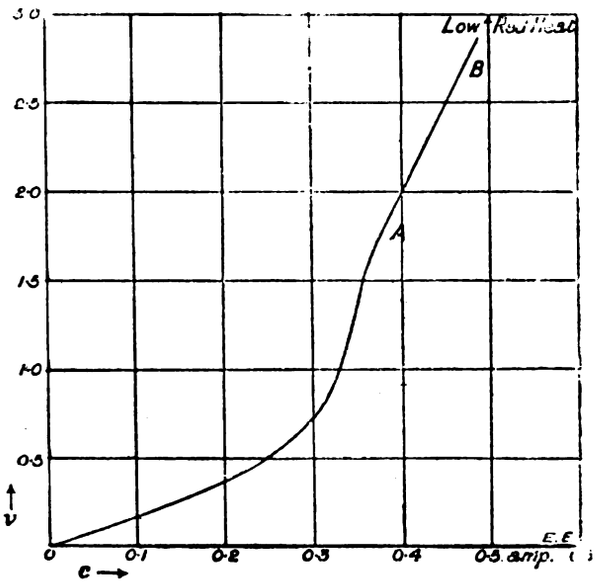

FIG. 11.—Nickel-Wire Diam. 0·05 mm. (2 mils.).

nickel wires of 0·15mm. (six mils) diameter. From a deflection of 100 divisions (400mm.) the light spot, after the switching off of the current, returned to within 1·5 divisions above zero in 30 seconds, and was still 0·5 division from zero after 75 seconds. This is prompt enough for many purposes, and it is no difficult matter to braze the junctions of such a thermopile. I have succeeded in brazing junctions of much thinner wire, and gained considerably in promptness of working, but this gain scarcely repaid the extreme difficulty of construction.

Method 10.—I may mention here a somewhat interesting null method of measuring continuous current which I have tried; it is shown in Fig. 10. The current passes, wholly or in part, through the thin wire, A, and also through B, a strip or rod of very low resistance. The heating of A by

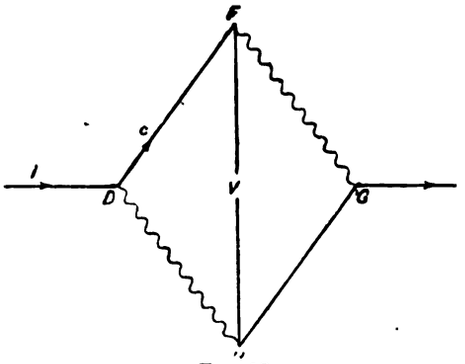

FIG. 12.

the current causes the pile, Th, to give an E.M.F., e, which is balanced against a part of the voltage drop along B by moving the slider, D, until the deflection of the detector galvanometer, G, is brought to zero. Here $e = k\,C^2$ and $v = r\,C$, r being the resistance of the fraction of B for which $e = v$. Then $r = k\,C$, and hence the graduations of the scale of the slider are directly proportional to the current measured.

SECTION D.—ON OBTAINING STEADY CURRENTS.

In accurate testing work it is of great advantage to be able to obtain very steady currents and voltages. By the help of an automatic thermal arrangement I have succeeded in obtaining very exact regulation, even when the supply voltage is varied

Digitized by Google

by 10 or 12 per cent. The method depends upon the alteration of resistance due to rise of temperature. In the following description I shall take a concrete instance with wires of nickel and manganin as typical of conductors of large and small temperature coefficients respectively. If a curve be drawn for any conductor showing the connection between c, the current through the conductor, and v, the voltage applied to its ends, the form of the curve will depend on the material of the conductor and on the temperatures to which it is raised by the current. It is convenient to call this curve the *characteristic* (*curve*) of the conductor. I assume that, in drawing the characteristic curve, steady conditions of temperature are reached at all points. For manganin, not overheated, the characteristic is practically a straight line whose steepness measures the resistance of the conductor, but for a thin wire of

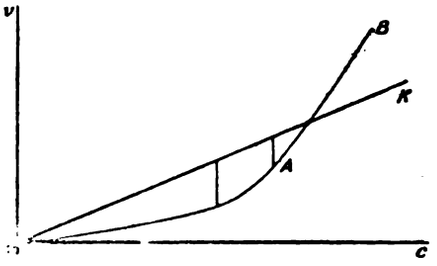

FIG. 13.

nickel the characteristic curve is of the form shown in Fig. 11, which is drawn from an actual experiment with wire of 0·05mm. (two mils) diameter. It will be noticed that the higher part of the curve (from A to B) is very nearly a straight line.

Method 11.—Now let a Wheatstone's bridge be arranged, as in Fig. 12, in which the arms, D F and G H, are equal resistances of nickel, while D H and F G (also equal to one another) are of manganin. In Fig. 13 let O A B and O K be the characteristic curve of D F and F G. Then it is easy to show that, as long as the branch from F to H is kept on open circuit, the potential difference from F to H, for any particular value of the current, c, will be proportional to the vertical distance between the two characteristic curves. It is easy to choose the relative values of the nickel and manganin resistances, so that O K shall be parallel to the straight portion A B, as in Fig. 14, and when this is the case $n\,m$ will be constant from A to B, and thus V will be practically constant for all values of the current, c, corresponding to the part A B. As I show in Appendix 2, this regulation also holds even when current is taken across F H the constant value of V, however, depending on the current taken. The construction for this case is shown in Fig. 15. O L is taken equal to C, the current through F H and L K is drawn parallel to the characteristic for the manganin wires; V^1 will

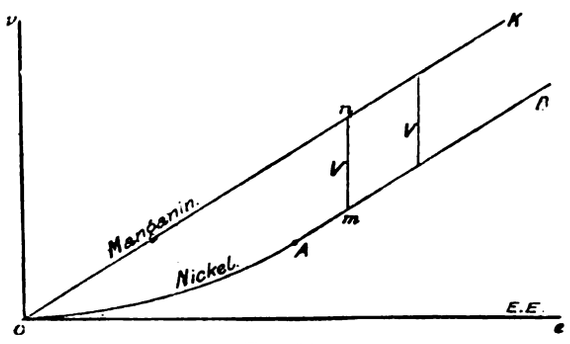

FIG. 14.

then give the value of the constant voltage from F to H. Thus it is possible to obtain very constant voltage and current, although the main current, I (Fig. 12), be drawn from a variable source, such as the mains of a supply company. With actual apparatus the maximum steady voltage which I have obtained has been about one-third of the supply voltage used; with alternating currents the use of a transformer makes this limitation of small moment.

Compensation for Variation of Temperature of Enclosure.—Unless the temperature of the enclosure containing the nickel wires can be kept constant, it is necessary to introduce compensation for temperature. This can be done by replacing part of each manganin resistance arm by copper (in the same enclosure as the hot arms), sufficient cooling surface being allowed so as to prevent undue heating by the current. The curves in Fig. 16 show the results of experiments at enclosure temperatures of 24deg. and 37deg. C. with a regulator compensated in this way. The arms of the regulator (in cyclic order) consisted of a two-mil nickel wire of 3·5 ohms; 20 ohms of manganin in series with 3·4 ohms of copper; and two equal manganin resistances of 125 ohms each.

It will be noticed that near 0·45 ampere both the regulation and the temperature compensation are satisfactory. The level part of the curve (Fig. 16) corresponds to temperatures of the nickel wire between about 400deg. and 600deg. C. It would,

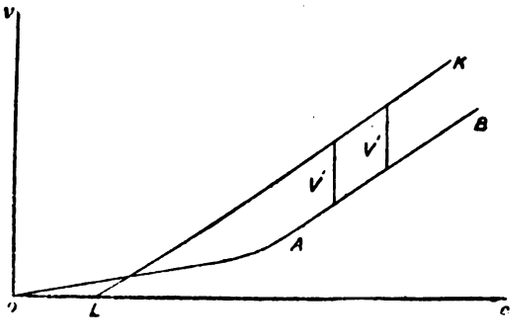

FIG. 15.

I believe, be possible to obtain more extensive and better regulation by using platinum or other material instead of nickel, since the nickel has an abrupt bend in its temperature resistance curve. Also, by replacing parts of the manganin

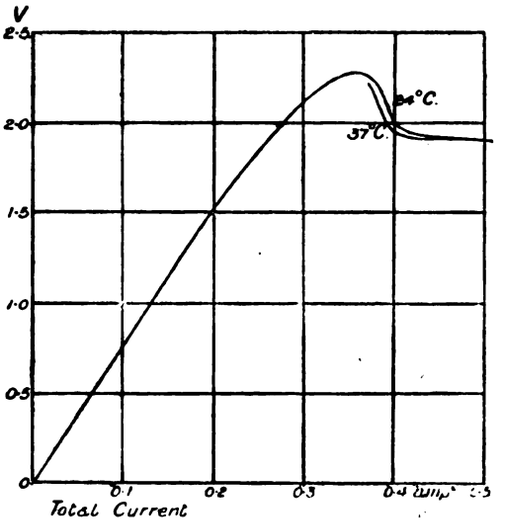

FIG. 16.

arms by heated nickel, say of larger diameter than that used in the other arms, it would be possible to make the upper characteristic bend up slightly, as in Fig. 17, and so to attain more exact parallelism of the two curves, and hence better

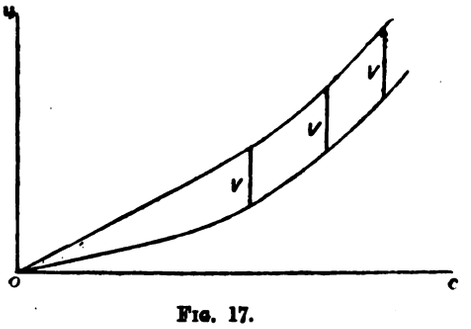

FIG. 17.

regulation. Again, by applying a once-regulated voltage to a second regulator a much greater steadiness would be obtained.

Method 12.—It will be noticed that in the above regulator the function of the Wheatstone's bridge is merely to obtain the

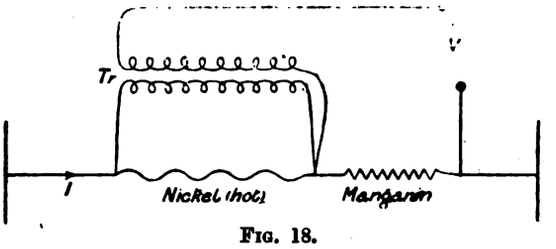

FIG. 18.

difference between the voltages on the nickel and the manganin resistances. With alternating currents the same may also be done by means of a transformer, as shown in Fig. 18, where the transformer, Tr, is connected so as to give a regulated voltage at V.

Digitized by Google

Uses of Regulated Voltages.—It is not difficult to find instances where regulated voltages would be of use in testing work. Standard incandescent lamps may thus be run at constant brightness. Shunts of watt-hour meters may be kept on constant voltage during test. With constant voltage, the mere measurement of the current taken by an inductive coil usually gives an approximate indication of the frequency. A constant current from a supply circuit may be used to get direct readings in a simple electric resistance thermometer.

SECTION E.—NULL METHODS OF MEASURING CURRENT.

If in the Wheatstone's bridge arrangement the resistances are so chosen that the characteristics intersect, as in Fig. 13, then we may obtain, for I and V, a curve such as that in Fig. 19, which is drawn from actual experiment (with direct

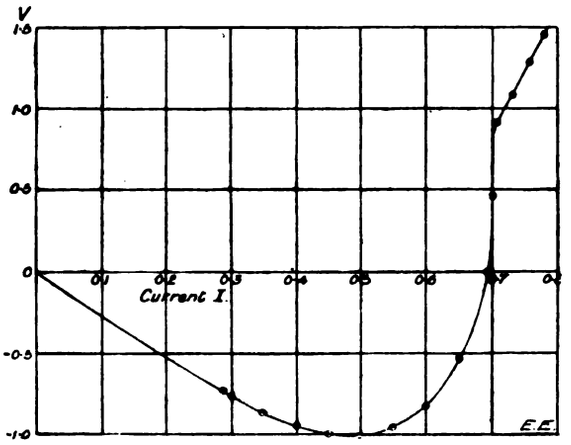

FIG. 19.

current). With proper temperature condensation V vanishes for a perfectly definite value of the total current, I, and if a sensitive detector be added the arrangement becomes *a thermal standard of current*. I have found a telephone with an intermittent contact in its circuit a convenient means of detecting the vanishing of V, the intermittent contact being of advantage even with alternating currents. The accuracy of such a standard is considerable.

Method 13.—If such a combination be put in series with a resistance having a part adjustable by a sliding contact, as in Fig. 20, it furnishes a simple null method of measuring a voltage—*e.g.*, of a supply company—which varies between small limits; the slider is adjusted to give silence in the telephone, and the corresponding value of the voltage is shown by the position of the slider. With alternating current the transformer method (12) is also applicable here, but a detector other than a telephone is necessary; for since the transformer alters the wave form slightly, it is found impossible to get any position of complete silence with the telephone.

Method 14.—In conclusion, I may point out that if a voltmeter be put across V (Fig. 12), it will be seen from the curve in Fig. 19 that a very open scale can be obtained corresponding either to the total current, I, or the outside volts; this furnishes

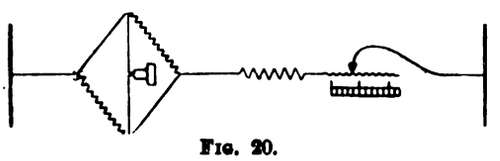

FIG. 20.

a thermally "set-up" instrument. I have found platinum better than nickel for this. Compensation for temperature can be applied as in the other methods.

APPENDIX I.

In connection with my remarks on the measurement of power, I should like to draw attention to an instrument invented by Prof. Riccardo Arnò for measuring the phase difference between two currents. It consists of two co-axial coils carrying the given currents, A and B, and a search-coil, S, connected to an electrodynamometer. (For simplicity, suppose A=B.) The main coils are by trial placed at such an inclination to one another that the search coil shows the same effective induced voltage in all positions as it is turned co axially to the other two. Prof. Arnò shows that with sine-curve wave-forms the angle between the main coils is then the supplement of the angle of phase difference between A and B. I proceed to show that, for any wave-forms (not containing direct-current components), the phase angle obtained is the power phase difference between the currents A and B. In Fig. 21 let the position angles of the three coils be as shown, O X, the initial line bisecting the angle A O B.

Let ϕ = angle of idleness between A and B;
2α = angle of position between main coils;
also let C = current in search coil;

then, by Fig 22, k C is the resultant of A cos $(\alpha+\theta)$ and B cos $(\alpha-\theta)$ at an angle ϕ.

Hence $$k^2 C^2 = A^2 \cos^2(\alpha+\theta) + B^2 \cos^2(\alpha-\theta) + 2AB \cos(\alpha+\theta)\cos(\alpha-\theta)\cos\phi;$$

$$\therefore 2k^2 C^2 = A^2+B^2+2AB\cos\phi\cos 2\alpha + [(A^2+B^2)\cos 2\alpha + 2AB\cos\phi]\cos 2\theta + (A^2-B^2)\sin 2\alpha \sin 2\theta.$$

If C = constant for all values of θ,

then $$(A^2-B^2)\sin 2\alpha = 0,$$

and $$\cos\phi = -\frac{A^2+B^2}{2AB}\cos 2\alpha.$$

Since $$A=B \quad \therefore \cos\phi = -\cos 2\alpha.$$ Q. E. D.

NOTE.—In the above I have assumed that there is no disturbing mutual induction between the search coil and the main coils.

APPENDIX II.

Mathematical Investigation of Bridge Regulator.—As in Fig. 24, let the equation to the upper straight part of the nickel characteristic be:

$$c = \frac{v}{m} + c_0,$$

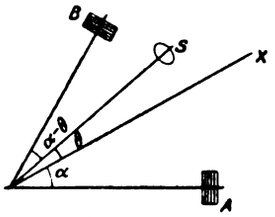

FIG. 21.

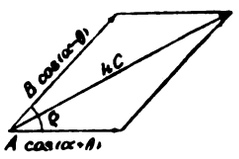

FIG. 22.

where c of course must be kept within its proper limits. If r = resistance of each nickel wire, then

$$\frac{1}{r} = \frac{c}{v} = \frac{1}{m} + \frac{c_0}{v} \quad \ldots\ldots\ldots \quad (1)$$

Now let the bridge potentials and resistances be as in Fig. 23.

Let V = voltage on R
= U − 2 v.

If the outer voltage U be variable, let us find the condition for V = constant.

We have $$v = \frac{U-V}{2} \quad \ldots\ldots\ldots \quad (2)$$

and $$\frac{v}{r} - \frac{V}{R} + \frac{v-U}{a} = 0 \quad \ldots\ldots\ldots \quad (3)$$

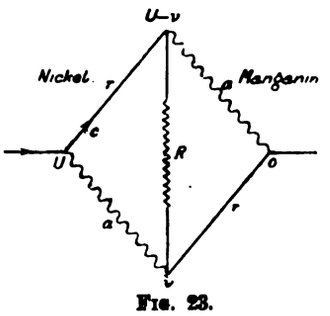

FIG. 23.

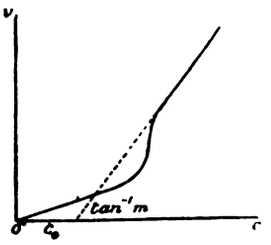

FIG. 24.

Hence, from (1) and (2),

$$\frac{U-V}{2m} + c_0 - \frac{V}{R} - \frac{U+V}{2a} = 0,$$

or, $$U\left(\frac{1}{m} - \frac{1}{a}\right) + 2c_0 = V\left(\frac{1}{m} + \frac{2}{R} + \frac{1}{a}\right)$$

Since V is to be constant,

$$\frac{1}{m} = \frac{1}{a} \quad \therefore m = a \quad \ldots\ldots\ldots \quad (4)$$

Hence $$V = \frac{2c_0}{\frac{1}{m}+\frac{2}{R}+\frac{1}{a}} = \frac{c_0}{\frac{1}{a}+\frac{1}{R}} \quad \ldots\ldots\ldots \quad (5)$$

also $$v = \frac{c_0}{\frac{1}{r}-\frac{1}{a}}$$

Thus we see that, whatever the value of R, the condition for regulation is simply that $m = a$—*i.e.*, that the characteristics of the nickel and the manganin should be parallel (for the upper straight part of the former). Equation (5) gives the value of the regulated voltage for any particular value of R.

NOTES.

Asphyxiation by Carbonic Acid Gas.—We note that a Bill will be introduced in the next session of the United States Congress, at the instance of the Allegheny County Medical Society, to authorise the asphyxiation of criminals sentenced to death by carbonic acid gas in place of the hangman's rope or the electric chair.

The German Visit.—We are informed that, in the unavoidable absence of the President, Mr. Alexander Siemens (past-president) will assume the leadership of the Institution party throughout the visit to Germany. Members are reminded that their applications for tickets should be forwarded before Saturday, June 15.

The Lancashire Motor Trials.—Referring to the trials of motor vehicles for heavy traffic which were made last week in the Liverpool district under the auspices of the Liverpool Self-Propelled Traffic Association, we understand that the judges have awarded a gold medal to each competitor in Classes A, B, and C. The awards in Class D will be announced n about three weeks.

Presentation.—The staff and employés of the Hammersmith Borough Council electricity works presented Mr. W. E. Brandreth, the late mains superintendent, with a case of drawing instruments and an illuminated address containing over 60 signatures as a mark of esteem on the occasion of his leaving to take up the position of resident engineer and manager to the Wycombe Borough Electric Light and Power Company.

The Longest Transmission Line. — The Bay Counties Power Company, of America, recently inaugurated what is stated to be the longest line for the transmission of electric power for commercial purposes in the world. The line in question extends from a generating station on the north fork of the Yuba River to Oakland, California, a distance of 140 miles. The current is transmitted at a potential of 40,000 volts.

Kew Bridge Works.—Through the courtesy of the engineers, Sir John Wolfe Barry and Mr. C. A. Brereton, a large party of the members of the Institution of Junior Engineers were enabled on Saturday last to pay a visit of inspection to the Kew Bridge works, which are now in active progress. The visit concluded with a cordial acknowledgment of the facilities which had been afforded the party for inspecting the operations.

Automobiles in the States.—The Automobile Club of America, we learn, have resolved to organise an annual road race, to be known as "The Automobile Club of America Sweepstakes," which will probably amount to about £1,000. The race, it is stated, will be international, open to competitors from all over the world. The first contest will, as at present arranged, take place in the middle of September next, probably over the Buffalo-Erie course. It has also been decided to organise an annual race for the mile record.

Arabian Telegraphs.—The Turkish Government have decided on further telegraphic extension in Arabia. The new line which is to be established will run between Bassora and Nedseh, which is situated in the interior of Arabia. The Ottoman Government also, we note, are taking action in the same direction. It is reported that they intend to connect the telegraph lines in the southern province of Yemen with the northern lines situated in the Hedjas. This new line will extend to close upon 800 miles. Starting at Lohija, it will pass along the coast of the Red Sea, and will reach its terminus at Lith, the south-west corner of the Hedjas. We learn, further, that the Turkish postal authorities have been granted a special credit to renew the submarine cables between Galata and Stamboul.

Wireless Telegraphy at Dover. — A Marconi wireless telegraphy installation is now being set up at Dover for the use of naval vessels only. This will be the first Government installation of Marconi's system on our coasts, but there is reason to believe that before long we shall hear of other well-known important seaports being provided with wireless telegraphy by the Government. The site at Dover is on the Western Cliff fortifications, overlooking the Shakspeare Cliff near the coastguard station. The mast will be in three sections, and when erected will measure 180ft. to the top.

Determination of the Specific Heats of Metals.—The *Journal* of the Chemical Society gives an abstract of some experiments carried out by Miss A. Serdobinsky and Miss A. Emelianoff for the determination of the specific heats of metals by their cooling rate. In their method the authors use a horizontal wire, the ends of which are fixed in rigid supports whilst the middle point is loaded to keep it taut. The wire is heated by the passage of a known current and then allowed to cool, the temperature at any instant being known from the length of the wire, which in its turn is calculated from the sag of the middle point. The authors' measurements yield for the mean specific heat of platinum the values 0·0319 and 0·0318.

Wireless Telegraphy for Canada.—Advices from Montreal state that the Canadian Government are considering the question of installing a system of wireless telegraphy as an aid to navigation in the Gulf of St. Lawrence, and to this end a series of tests are shortly to be carried out. Federal officials having examined the system in use on the steamship "Lake Champlain," instruments have been cabled for to England for the purpose of the proposed experiments. According to present intentions, one operator will be placed at Belle Isle and another on board a Government steamer. The general opinion among shipping men in Montreal is that the installation of the Marconi system, for instance, would reduce the dangers of navigation at the entrance to the St. Lawrence by 75 per cent.

Alternating-Current Integrating Meter.—We are pleased to hear that the Board of Trade have now finally approved of the Shallenberger alternating-current integrating wattmeter for the measurement of electrical energy when supplied on the constant-potential alternating-current system, and also that they further approve of the means provided for fixing these meters and for connecting them with service lines. The meter specifications and instructions were deposited at the Board of Trade by the British Westinghouse Electric and Manufacturing Company, Limited. We are particularly pleased to note that one more meter has been added to the list of the few previously approved by the Board of Trade, and, in view of the severe tests to which these meters are put, consider it a great compliment to the firm.

Osmium Lamps.—Some experiments have recently been carried out in order to test the relative efficiency of osmium lamps with ordinary carbon lamps. In one test four 25-volt osmium lamps in series and four 100-volt carbon lamps in parallel were arranged on a 100-volt circuit, and both gave the same illuminating power, but the osmium lamps consumed only 40 per cent. of the current required for the ordinary lamp. In another test an osmium lamp consuming energy equal to 24 watts gave a light of 20 c.p., while a carbon lamp with the same consumption gave a light of only 6 c.p. Osmium lamps can be made to give a light of from two to two hundred candles, and lamps that have become darkened can be restored without renewing either

Digitized by Google

the bulb or the filament. The supply of osmium is becoming rather limited, and the question still remains as to how far the price of the metal is prohibitive.

Tynemouth Electricity Works.—With respect to our description of the electricity works belonging to the Corporation of Tynemouth which appeared in our last week's issue, we understand from Mr. C. Turnbull, the borough engineer, that the following slight correction should be made in our notes. It is with regard to the arrangements for stopping and starting the pump, drawing water from the hot-well, and forcing it up to the top of the cooling tower. The automatic arrangements which we described and illustrated are to be slightly altered so that the pump is not actually stopped as the water-level falls, but is slowed down so as to draw the water at a slightly slower rate. It will be readily seen that this will be a decided improvement. With respect to the diagram of the regulating switches for the accumulators, these were actually put on the neutral side of the cells, and hence were not arranged quite as shown in the diagram.

Motorcars for the Army.—The question of providing the British cavalry in South Africa with remounts has apparently had the effect of sharpening the wits of some of our legislators. In the House of Commons, for instance, an hon. member hit upon the brilliant idea of substituting motorcars for horses, observing the while that they could go into places where horses could not proceed, that they could move faster and carry heavier goods. A charge of cavalry mounted on motorcars would certainly be something more than unique, and the spectacle of mounted Boers being pursued over kopjes by motorcars brought forth some jocular remarks from the hon. members assembled. Later on, however, it was stated that the Government are alive to the importance of motorcars for transport purposes, and are now conducting experiments with a view to their utilisation in the army. In connection with this, we may mention that representatives of the War Office were present at the recent Liverpool trials, and watched the results throughout.

Electric Tramway Switch.—In the *Street Railway Review* for May 15 the description is given of an automatic electrical and mechanical track switch which is being introduced by the American Electric Switch Company, of Pittsburg. The arrangement of this switch is such that the driver of the electric cars can operate it, and in this way the expense of keeping a pointsman at the turn-outs is avoided. The switch is operated by means of a solenoid, through which the current to the tramcar is passed. A small section of the trolley wire, about 20ft. from the switch point, is insulated from the rest of the trolley wire, and all current going to this small section is passed through the switch. If, then, the driver keeps the current on as he goes over this small section the electric switch will be operated, and he will take the turn in the track in one direction. Should, however, he desire to go straight on, he will not take current from the line when going over this section, and the switch will remain in its normal position. A drawing is given of the apparatus in our contemporary, but the essential details of the gear require larger illustrations to make them clear.

Theft of Electric Current.—The issue of *Electricity* for the 15th inst. refers to the case of a farmer located near New Egypt, N.J., who is being sued by the Bordentown Trolley Company for the larceny of electric current. It seems that for some time the trolley company has been wondering how it happens that it required a greater amount of electric current to run the Bordentown branch than it did to run any other road of similar length and grade in the country. After considerable investigation by electrical experts, it was discovered that the ingenious Bohemian farmer referred to above had tapped one of the main feeders, and was utilising the current thus obtained to stimulate the growth of certain crops on his farm. A perfect network of wire was discovered under a certain patch 300ft. long by 200ft. wide in which radishes were grown, which are claimed to have matured in 19 days, whereas radishes grown under ordinary conditions required six weeks. This raises a nice point for the consideration of the court. Our contemporary suggests that the question for the judge to decide is, what number of amperes of current equals one month's natural growth of a radish in a sandy soil?

Comparative Testing of Fan Motors.—Mr. S. D. Gilbert contributes to the *American Electrician* a short description of a device he has used for testing fan motors to find out which circulates most air with the least consumption of energy. In our opinion, the apparatus used does not find out what is required, because the means of carrying out the test interposed resistance to the current of air, which may entirely alter the working of the fan. The device consists of placing a large disc pivoted on a knife-edge opposite the fan and about 1ft. from it. The motor is then run up to speed, and the lever on the disc counterweighted until it occupies the same position as before. The weight required to keep it in this position is then used as a means of ascertaining the work done by the fan, while the energy given to the motor is measured in the usual way. While with the same class of fan and the same pitch of blades the apparatus may give some idea of what is being done, the method is quite incapable of giving any reliable results when the above-mentioned conditions are varied. In any case, the fan will deliver much less air with the disc in front of it than it would do if delivering into an ordinary room.

An Aerial Machine.—A new flying machine, which has been built in "great secrecy" by Messrs. Denny Bros., of Dumbarton, has recently been experimented with, and is reported to have given much satisfaction. The owners of this machine are two Spanish gentlemen, father and son, who apparently are extremely anxious that no details shall leak out, and in order to observe strict secrecy the trials were carried out in some private grounds. Notwithstanding these precautions, however, some particulars of the machine have appeared in the daily Press. We are told, for example, that the mechanism is somewhat after the style of that adopted by Mr. Henry Suter, of Zürich, having a pedal arrangement. This form of engine was adopted in preference to a petroleum engine after repeated experiments. The flying machine itself measures 40ft. from tip to tip of the wings, and the weight, including that of the driver and steerer, is about 6cwt. The trials are said to have been attended with much success. The machine rose steadily, and demonstrated the accuracy of the principle on which it is made, although the driving power was inadequate to cause the wings to flap and oscillate.

German Patents.—As in the case of this country, a considerable increase is shown in the number of applications for new patents in Germany during the past year over the previous 12 months. This increase amounts to 845, the number of applications received at the German Patent Office during 1900 standing at no less than 21,925. The subjects in respect of which this augmentation is particularly noticeable include the electro-technical, lighting, printing, and metallurgical industries. As regards the patents granted during this period the figure is put at 8,784, as against 7,430 in the previous year and 5,570 in

Digitized by Google

1898. After the cancellation of 19 patents, there remained still in force at the end of the year 25,115 patents. A large number of the applications for new patents to the German authorities came from abroad—viz, 1,734 from the United States, 1,307 from France, 1,034 from Great Britain, and 1,029 from Hungary. The average life of a patent in 1900 was 4·7 years. At the present time, however, there are no less than 114 patents in existence which were granted in 1886. In the course of the present year these will expire. It will be seen from the above figures that the number of patents granted to inventors in Germany is continually on the increase.

The Development of Cuba.—With the conclusion of the war between Spain and the United States, the development of the island of Cuba was energetically begun. While, on account of the policy of the United States Government, American investors have been discouraged in this work, English, German, and companies of other nationalities are carrying out plans for public improvements in Cuba, recognising, as they do, that satisfactory terms will sure to be granted to them before long. The *Street Railway Review*, dealing with the subject, refers to the reports from Cuba concerning the progress made by Sir Wm. Van Horne in carrying out his electric railway enterprises in the island. An old law provides that the owner of land may build such railways as he sees fit thereon, and, owing to the general franchise law being suspended, Sir Wm. Van Horne has purchased whole farms contiguous to each other along the routes of the proposed lines, thus getting rid of the difficulty of obtaining the consent of the United States Government. The Cuban municipal authorities, on the other hand, have been very ready to grant rights over their streets, and the only obstacle is as to crossing the highways between plantations, which highways are under the control of the United States War Department.

New York Tramways.—The cable tram in New York has had its day, and last week saw the whole system of cable trams on the Broadway route supplanted by the more modern and popular electric cars on the conduit system. The effect of the sudden change on the public was one more of surprise than anything else, for the whole transformation was all effected in one day, whereas the general opinion was that the cars could not be put on the road for a week. New Yorkers are, therefore, loud in their praise of the skill and energy which has been shown by the tramway company on this occasion. While this is generally admitted, however, we find that in the technical Press of New York the change, as a change, is regarded as being rather late in the day. The *Electrical World*, for example, informs us that some 10 years ago, when the cable was going in, they entered a vigorous protest on the ground that it would soon have to come out and be replaced by electricity, and the editor maintains that an electric conduit system could have been successfully put in at that time on this route. Referring to the trials now being made with compressed-air cars in New York, the editor regards them as an even worse failure than the cable cars, and ends up by deploring the fact that time and money should be wasted in the effort to substitute them for electricity, which is emphatically the "all-conquering, all-sufficient agent of modern traction."

American Engines.—According to some information which has been collected by our enterprising contemporary, the *Daily Mail*, the Midland Railway Company have not found that the American locomotives compare at all favourably with those of English make. The local superintendent of the line, Mr. S. W. Johnson, has reported that American engines consume at least 20 per cent. more fuel and 50 per cent. more oil than engines of English make doing the same work. Mr. Johnson also states that the repair bill is some 60 per cent. higher for the American locomotives. The first two items, of course, are serious matters on any line, but we should not be surprised to find that with regard to the repairs, the extra cost is partly due to the fact that they have to be made on a locomotive the parts of which are made, not to English standard, but to American. This would certainly increase the cost of making such repairs. The other point, however, in connection with engine repairs may be that the American manufacturers are not using the same care as their English contemporaries in the selection of the materials used in the construction of locomotives. Central-station engineers who have had experience with stationary engines made in America have in certain instances already found that this is the case, and that while they can get more prompt delivery by sending their orders across the Atlantic, there is evidence that for length of life English-made engines have a great advantage over those made in America.

Teneriffe Electric Tramway.—The United States Consul Berliner, writing from Teneriffe, Canary Islands, announces the inauguration of an electric tramway line connecting the port of Santa Cruz with the town of La Laguna. In addition to passengers, it is anticipated that considerable traffic will be forthcoming in connection with the carriage of fruit, which is the main export from the island. The power house is situate at La Cuesta, about halfway between the two towns, and at an elevation of 960ft., La Laguna being 1,804ft. above the sea-level. The tramway, which consists of a single track, is on the overhead trolley system, both wood and iron poles being used in the country. In the towns span wires are strung over the street from house to house. The concession for the line includes the whole of the road between Santa Cruz and Oratava, and from the present terminus there will be a regular service of automobiles to the town of Oratava until the extension is completed. The total length of the line will then be some 27 miles. The company having the work in hand is the Compania Electrica de Tramvia de Teneriffe, and has a capital of over £61,760. Another Belgium company has also obtained a concession for an electric double-track system between the ports of Luz and Las Palmas, in the island of Grand Canary. This road will run along the seashore, and extend from four to five miles. In a way, this line, when constructed, will be the more important of the two, as Las Palmas is practically the principal town in the Canary Islands, and is doing considerably larger business than Teneriffe.

A Successful Railway Swindler.—The *Street Railway Review* for May tells of a notorious railway swindler who has just been sent to prison in the States for practising a number of successful frauds on the steam and electric roads and accident insurance companies in America. For the past 10 years this man, who bears the name of Moffett, has carried on an ingenious system of swindling by pretending to get hurt on a train and then compromising with the railway company, or by taking out an accident policy, claiming to be hurt and collecting on the policy. The curious fact in connection with this man's career is that he himself once filled the position of manager of a large insurance office in the States. With the assistance of an accomplice, he has practised these frauds on very nearly all the railways in the States, as well as succeeding in swindling as many as 21 insurance companies. Both men were aided in these swindles by the fact that each had an ununited fracture of the ribs, and thus could always get a doctor to certify that they found broken ribs. One of the many different schemes Moffett practised was that

Digitized by Google

if he heard of a runaway or a train wreck he would at once go to bed, summon a doctor, and pretend to have been injured in the accident. He had a complete list of all the railway claim agents and insurance adjusters in the country, and he lost no time in notifying them when he chose to get hurt. He always made it a point to get the best doctors to attend him, as he stated in a confession made after his conviction that they were the easiest deceived, and insurance offices were quite willing to accept their statements without question.

Motorcar Demonstration.—The policy adopted by the Automobile Club of giving practical demonstrations of the powers, advantages, and possibilities of motorcars to public authorities who would reduce the speed to 10 miles an hour, etc., is certain to win in the long run. Our readers may remember that some short time ago the club arranged a demonstration in Essex solely for the benefit of the county councillors and representatives of the local authorities, and that in several quarters the invitations were refused on the ground that they "wished to preserve an open mind on the subject." This, however, would not seem to be the feeling on the occasion of the last invitation sent out by the Automobile Club. The result was that some 250 county councillors from all parts of the country have, during the last three days of the past week, been indulging in rides from the clubhouse, in Whitehall-court, to Sheen House, Richmond, on motorcars lent for the purpose by members. From the tenor of the speeches at the luncheon which followed the drive to Sheen House on Saturday, it seems pretty clear that many of the prejudices which have heretofore governed the minds of the various county councils in this matter have been to a great extent removed. The company of 300 members and guests of the Automobile Club included Earl Grey (in the chair), the Duke of Northumberland, Sir Arthur Arnold, and others, and it was generally admitted that the drivers of the motorcars had proved themselves to have complete control over their vehicles. Some pleasant rides through Richmond Park were afterwards enjoyed, and the day's proceedings concluded with the drive back to town.

Army Reform — Proposed Advisory Board.—Major-General Webber, C.B., read an interesting paper on Monday night before the United Service Institution on the vexed question of army reform. In an address which lasted over an hour the lecturer advocated in the strongest way the necessity for the establishment of a Board, the members of which should be selected from the services, be appointed by the Crown, and be as independent and as permanent as the members of the judicial bench. The object of such a body would be to enable a standing joint committee of both Houses of Parliament, for instance, appointed to consider all questions of offensive defence, to have direct access to the best and most experienced sources of advice without the intervention of Ministers who are members of a party Cabinet; the ultimate object of it all being to bring the mind of the British public in direct contact or connection with the mind of a group of selected professional sailors and soldiers, placed so as to be outside all questions of party politics. The only portions of the Admiralty and War Office administrations which General Webber would transfer to the control of this new body are their respective intelligence departments. There was no question in his mind that the conditions of the armie in France, or America, or Germany, or Russia, produced the only real business-like results as regards the efficiency in everything for which an army exists. General Webber proceeded to show how traditional and contemporaneous parliamentary procedure gave no precedents conflicting with his proposals, and how the Government of the day would be relieved of responsibility which at present is always interfering with the true functions of the advisers of the Crown. He dwelt on Colonial defence, and the confidence which such an Advisory Board would give to men's minds throughout the Empire. It should be remembered that General Webber's proposal does not conflict with Mr. Brodrick's proposals now before the country. On the contrary, the existence of a permanent Advisory Board would, in General Webber's opinion, subject those proposals to instructed criticism, and help to safeguard the continuity of the application of all that is best in those proposals.

A Water Rheostat.—The *Electrical World* of New York in its issue for June 1 devotes an article to the description of a water rheostat now in use at the Pan-American Exhibition for bringing gradually up to candle-power the 200,000 8-c.p. incandescent lamps which furnish the decorative lighting at the exhibition. This is the first attempt, it is said, to bring up slowly or gradually reduce in candle-power such an immense body of lights simultaneously. The location of this big rheostat is at the western edge of the grounds, where the 11,000-volt Nigara transmission line enters. The rheostat-house, which is built on stilts about 15ft. high, contains three tanks of water, one for each leg of the circuit. The transmission line supplying the exhibition, it may be stated, consists of two three-phase circuits. The water-tanks referred to are all mounted on porcelain insulators such as are used on the line. Into each of these tanks a cast-iron plate operates to vary the resistance in circuit. The plate is pivoted in such a manner as to describe the arc of a circle while being lowered into the water. When quite in the water the tip of the plates strikes a submerged clip, or switch jaw, which short-circuits the rheostat. The increase of candle-power of the lamps from the dullest red to full brilliancy is said to be very steady, except that there is a sudden rise just before the plate, which is lowered by an electric motor working on a worm gear, strikes the submerged clip. To bring the lamps up to full candle-power occupies only 45 seconds, while in shutting down some 75 seconds is taken. From the appearance of the lamps the voltage at the start is said to be not over 20 per cent. of the full voltage. Calculations show that, assuming the 200,000 25-watt lamps take one-fifth their normal current and voltage at the start, the rheostat takes 800 kw. The lip at the pivot end of the cast-iron rheostat plate is always under water, and the circuit is broken by the main oil switch in the electricity building. It was found impracticable to break the arc at the rheostat, or even to allow the plate to come the least bit out of the water, as the resultant arc would stream all over the neighbourhood. The rheostat is used only for turning on the lights at the grand illumination at 8 p.m., and for turning them off for the night later on.

A Steam-Driven Transmission Plant.—An article by Mr. J. R. Cravath in the *American Electrician* for June has considerable interest, in view of the information given with respect to the transmission of energy for electric lighting over a considerable area with steam-engines as the prime mover. The plant in question is situated at Santa Monica, and the generating station is connected up by transmission lines to Long Beach, Terminal Island, San Pedro, and Redondo. The voltage used in the transmission is 22,000. In each of these four places small steam plants were previously used for electric lighting, and by supplying them from a common transmission scheme a saving in fuel and labour of 50 per cent. has been made. The large generating station is placed on the Santa Monica beach, and serves the North Beach bath-house with hot salt water

Digitized by Google

from its condensers, in this way gaining an additional source of income. The electricity is generated at 60 frequency and 2,200 volts, and then transformed up for the transmission lines by means of oil-cooling transformers. The whole of the power is now used for electric lighting, but we understand that there are some irrigation works on the line of route which employ some 800 h.p., which are almost sure to come on to the mains. The longest distance over which the current is transmitted is 35 miles. The transmission line consists of three No. 6 medium hard-drawn copper wires on "Provo No. 1" glass insulators furnished by the Hemingway Glass Company, of Covington, Ky. These insulators get their name from the 40,000-volt transmission plant at Provo, Utah, where they were first employed; they are 7½in. in diameter. There are also some Locke insulators. The insulator pins are 12½in. long over all, 8½in. from the top to the shoulder, and raise the insulator 4in. from the cross-arm. They are made high to prevent leakage from the edge of the insulator to the cross-arm. The cross-arms and pins are boiled in linseed oil. The cross-arms are 44in. long, and carry a pin on each end; the distance between wires is 34in. The top of the pole is bound with iron wire, and bored to receive a pin which carries the top wire of the three-wire triangle. The line is transposed every mile. The poles are spaced 130ft. apart; they are 35ft. long in the country and 40ft. long in the towns. The line is designed to transmit 300 kw., and is now carrying 150. The apparent energy required to charge the line is 34 kw. The voltage is 16 per cent. higher at the far end than at the Santa Monica power-house, due to the capacity of the line.

Municipal Supply in Bulk.—In our issue for May 24 we gave the gist of the resolutions passed at the conference held between the representatives of the various local authorities in Greater London and the London County Council to consider the general question of the legislation affecting generating stations for the supply of electricity in bulk. It was decided at this conference, among other things, to draft a Bill to confer certain powers on the County Council, and we now gather from the agendas of the various local authorities concerned that the following are the lines upon which it is proposed to draw up the Bill. In the first place, a clause is suggested to the effect that "Where a company or person is authorised under the Electric Lighting Acts, confirmed by Parliament, to supply electricity within any area extending into the district of more local authorities than one, such authorities may combine for the purpose of purchasing the undertaking of such company or person, whether by agreement in anticipation of the date at which powers of compulsory purchase may be exercised, or compulsorily at such last mentioned date, and in any such case the London County Council, with the consent of the local authorities of the districts concerned, may either by agreement in anticipation of the date of compulsory purchase, or compulsorily at the date of compulsory purchase, purchase the undertaking of such company or person." In the second place, it is proposed that "Where either by agreement or compulsorily the London County Council shall have purchased the undertakings of any such company or person, the Council may by agreement with the local authorities concerned, either manage and carry on the undertakings or any part thereof, or transfer the same wholly or in part to any such local authority or authorities." Thirdly: "Where a company is constituted for the purpose of holding lands or providing a station for generating electrical energy and for supplying electrical energy to any other company, body, or person, and such first mentioned company is not a company supplying energy directly to persons consuming the same, the undertaking of such first mentioned company shall become subject to purchase at the times and upon the terms prescribed by Section 2 of the Electric Lighting Acts, 1882 and 1888, provided that in lieu of the period of 42 years from the date mentioned in Section 2 of the Electric Lighting Act, 1888, there shall be substituted a period of 42 years from Aug. 26, 1889." And, fourthly: "Where the London County Council shall have purchased the undertakings of any such first mentioned company, the Council may either manage and carry on the undertakings or any part thereof or transfer the same wholly or in part to any local authority or authorities."

South Wales Power Scheme.—An interesting review of the progress made and the work yet to be carried out in connection with the South Wales Electrical Power Distribution Company's scheme appeared in a recent issue of the Cardiff *Western Mail*. Mr. G. L. Addenbrooke, managing director of the company, who is responsible for the article, first refers to the position of the company in relation to the Rhondda Urban District Council. A satisfactory agreement between the two bodies has been come to, the outline of which is that the Council allow the company to supply electrical energy for power purposes throughout the Rhondda district, but the company are prohibited from applying for a provisional order for lighting purposes without the consent of the Council. At the same time, in the event of the Council determining to supply their own electric light, a schedule of rates has been agreed upon, under which the company are to supply the current wholesale for distribution by the Council. With regard to those local authorities who obtain provisional orders this year, the position is equally beneficial to the company. Although these councils may erect their own generating stations, this will not prevent the company bringing mains into their respective districts, so that the users of power will be certain of getting the cheapest possible supply. Turning to the work which the company have in hand, the ground has now been sufficiently cleared to enable them to get on with the engineering part of their project. After careful consideration, and on the advice of Messrs. Bramwell and Harris, the consulting engineers, it has been determined to erect, in the first place, a large station in the neighbourhood of Pontypridd. Plans and estimates have been prepared for this station, which it is intended shall have a capacity of 12,500 h.p. to commence with. Excluding spares, this will permit 10,000 h.p. to be used at once for supply. The voltage on the trunk mains proceeding from the station will probably be about 10,000 volts, which will practically enable any point to be reached in the company's area, though as soon as the load grows and circumstances warrant steps will be taken to commence operations on the other sites which were scheduled in the company's Act, near Pontypool and Neath, so as to relieve the load on the central station. As far as can be predicted, the work of erecting the station and laying the mains will take about a year from the date of the sanction of the Board of Trade being received. This is expected within the next two months. Mr. Addenbrooke then goes on to refer to the several other power schemes which are in progress or projected, with a view to showing that there is now a general movement in this country to initiate electric power supply over all the great industrial districts. He concludes with the hope that the people of South Wales seeing the advantages which such a supply of power over their area will give, and wishing to be in the forefront of the districts in the United Kingdom in which such facilities can be obtained, will do all that reasonably lies within their power to help the legitimate enterprise of the company and facilitate its progress.

THE COMING VISIT OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO BERLIN.

(Continued from page 815.)

The Cable Works of Messrs. Siemens and Halske on the Nonnendamm.

The new cable works of the Siemens and Halske Company, which were put into active operation on August 1, 1899, is situated between Charlottenburg and Spandau, on the northern shore of the Spree, and can be reached in about 20 minutes from the Jungfernhaide depôt of the Berlin Ringbahn. Goods are brought to the works by water as well as by railway. For this purpose a canal has been cut which extends from the Spree to the factory. Fig. 2 shows this canal, whose dock is equipped with an electrical travelling crane. The railway traffic between the freight depôt, west end, and the works is effected by a steam ferry, which transports simultaneously two railway cars (see Fig. 1). After their visit at the dynamo works at Charlottenburg, the British guests of Messrs. Siemens and Halske will be conducted on board a special steamer placed at their disposal for the purpose of going down the Spree, which here passes through a lovely landscape; and after having partaken of lunch on board, they will be landed at the cable works at Nonnendamm.

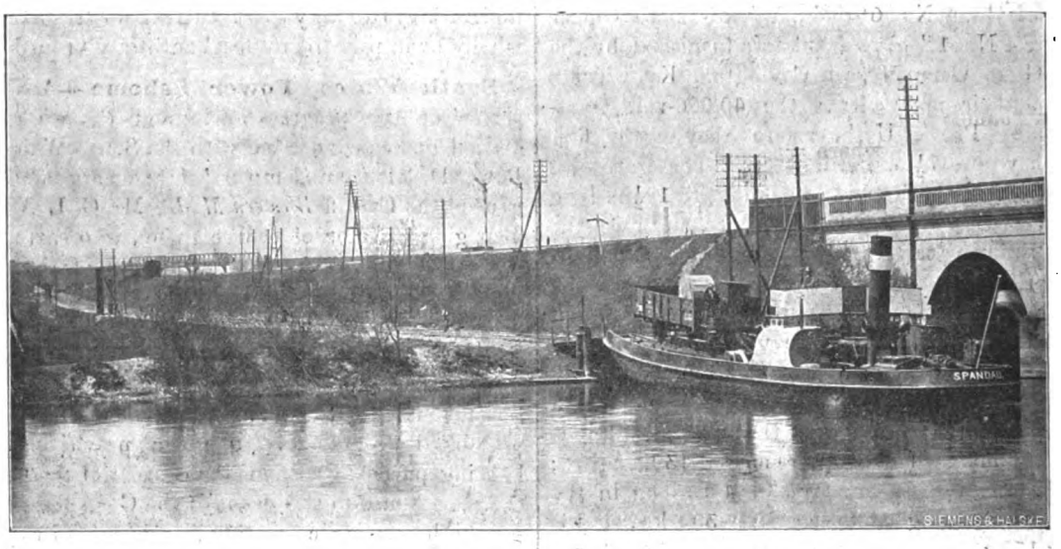

Fig. 1.—Steam Ferry.

The cable works, constructed on piles, consist of a horseshoe-shaped edifice, which in its inner open yard contains a number of extended halls connected with the whole building. The workshops, sample-rooms, and offices are also in close touch with each other, which is especially valuable in a cable works, as the transport of half-finished cables over an open court exposed to the weather is thereby avoided. An extension of the works is possible by adding a western addition to the establishment. The manufacture takes a course from north to south, and each north-southerly extending field of pillars in the halls forms in some measure a little cable works of its own. It is, therefore, possible by the addition of one or more rows of pillars to enlarge the works as far as is desired. The cable works is used for the manufacture of lead-covered fibre cables, produced principally in the halls and connecting rooms. In addition, guttapercha and rubber covered cables are made in the main building, and for telephone purposes cables insulated with paper are also manufactured. Covered and braided wires of different kinds for installation purposes and for the building of machines and apparatus are also largely manufactured.

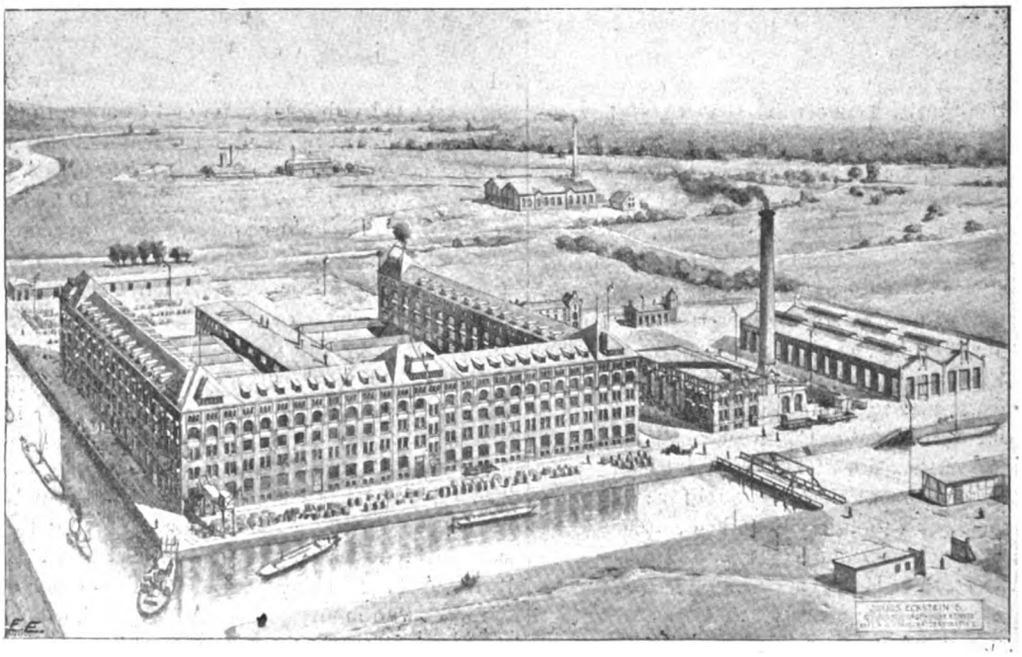

Fig. 2.—View of the Cable Works.

Manufacture of Heavy Cables.—The manufacture of heavy cables begins in the hall. After the wires have been given out from the stores they are taken to the wire-winding drum, where they are put on coils—the so-called bobbins which fit into the cable machines. Then in the stranding department the copper wires are united on the

Digitized by Google

cable-stranding machine (see Fig. 3 and Fig. 3A), and finally are covered with the insulating material, jute usually being used. Next to the stranding department are the impregnating and lead-pressing rooms, situated in

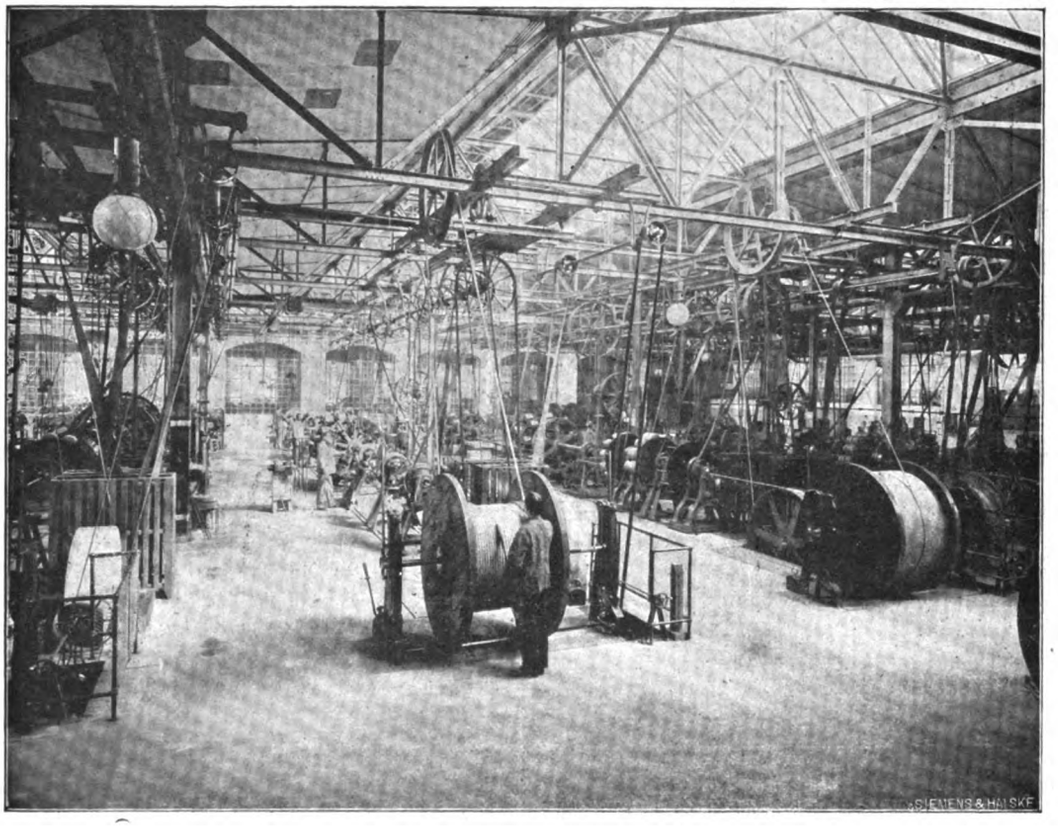

FIG. 3.—Stranding Machine.

the middle part of the halls. Here the cables covered with jute in vacuum drying boxes are cleared of moisture, and then in large kettles most thoroughly impregnated and insulated. Fig. 4 shows in the background such drying

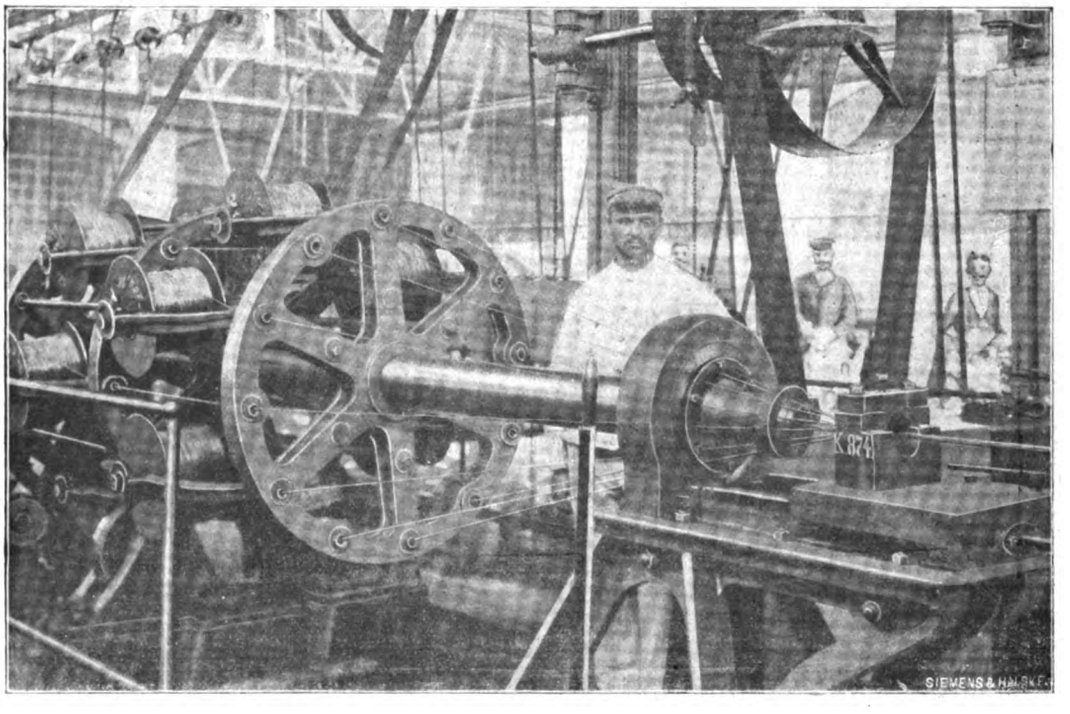

FIG. 3A.—Stranding Machine.

apparatus, while in the foreground the round impregnating vessels are observable. From the kettle and the melted insulating mass the cable rises direct to the lead press, and is covered there with a seamless lead mantle. Fig. 5 shows a lead press, in which the lead has been warmed in such a way so as to be in a plastic condition. Besides a number of cold-lead presses, there are hot presses which, under pressure, squirt the lead out of a cylinder round the cable. After the cable has been thoroughly lead covered, it is carefully tested in the testing-room to make sure that the insulation is complete and effective. By these measurements the fact is thoroughly established whether or not the lead covering has been made totally tight—*i.e.*, capable of withholding the entry of moisture into the insulating fibre. The cable during testing is placed into a tank. If the testing proves the perfectness of the cable, that shows the satisfactory working. Furthermore, in order to protect the armature against damaging

Digitized by Google

influences of the earth wherein the cable is to be placed, it is covered with fibre and insulated, as shown in Fig. 6. After the cable finally, in order to prevent sticking, has been drawn through a bath of lime-water, it is wound on large wooden drums, and taken to the southern end of the hall, where the different lines of manufacture are brought for shipment. The production of the heavy cable department includes, of course, the manufacture of heavily protected cables, such as submarine and subfluvial cables, and also mine cables on a very large scale. Messrs. Siemens and Halske have supplied a considerable number of mines on the Continent of Europe with these latter, as well as in South Africa and Asia, where they have been called upon to erect many complete electrical mine plants.

Manufacture of Guttapercha and Rubber Cables.—Since it was discovered that guttapercha was a very suitable insulating material for earth cables, its use for subterranean and submarine cables has assumed enormous proportions. Guttapercha cables are manufactured in the following manner: The guttapercha, by heating and by the use of a kneading machine, is softened to a plastic condition. The soft guttapercha goes into a press, which has a strong resemblance to the lead press previously mentioned, and by the use of suitable mouthpieces the guttapercha is pressed around the wire. Fig. 7 shows such a machine. After the wires have received a coating from the press shown standing in the background, they are run over pulleys partly through the air and partly through water, in order that the

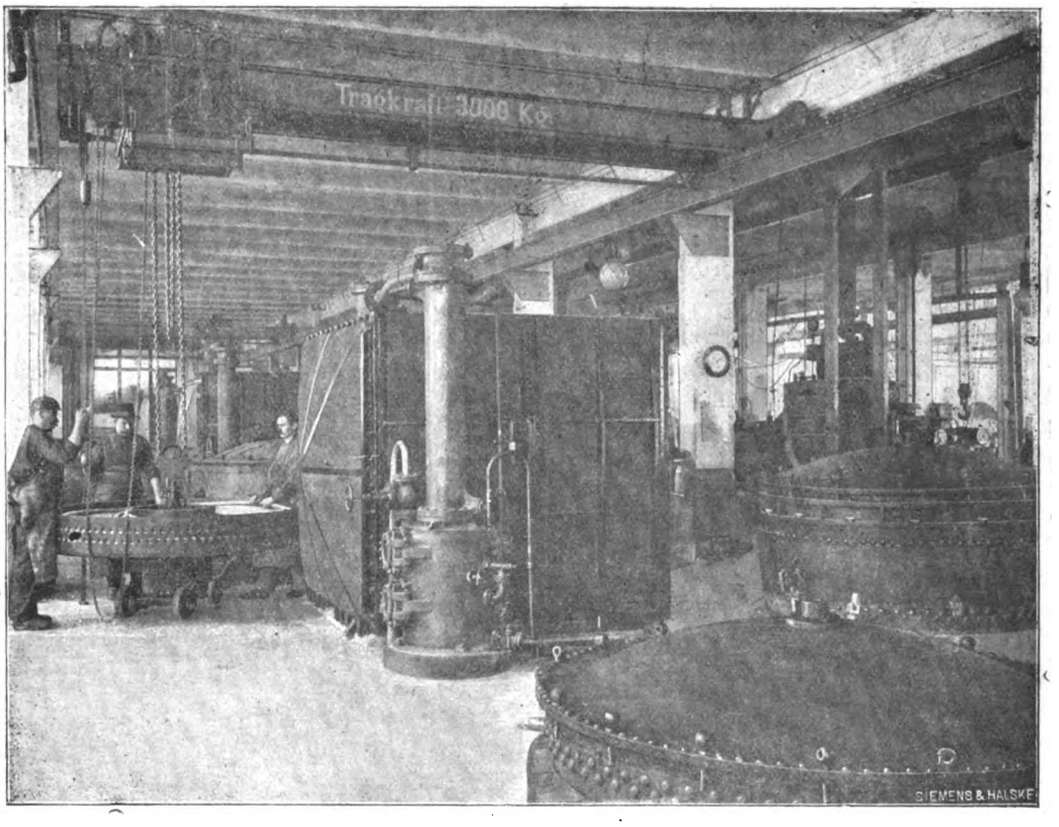

FIG. 4.—Drying Boxes.

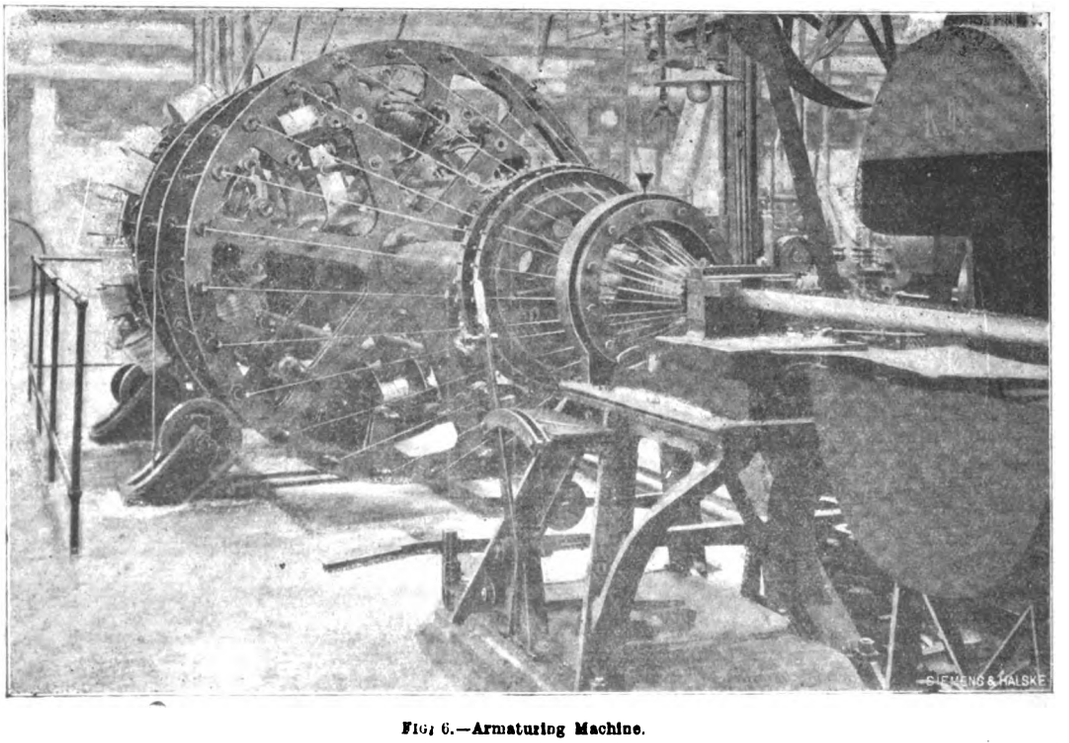

FIG. 6.—Armaturing Machine.

Digitized by Google

guttapercha may be hardened. Owing to the high price of guttapercha, other substances of the rubber kind, especially indiarubber, are used in the manufacture of cables. In the production of cables of indiarubber, vulcanising the rubber is necessary. For this purpose the rubber is kneaded together with sulphur or sulphur-holding material. In the later course of production, by proper heating the sulphur is united with the rubber, taking from the latter its sticky properties, and giving to the manufactured article many of the valuable qualities possessed by guttapercha. The indiarubber cables, just as the guttapercha cables, are made by pressing the material around the wires. The wires, by special machines, are often put between two indiarubber bands and rolled in a mould. Sometimes the wires are covered with rubber bands, just as would be done with silk or other insulating material.

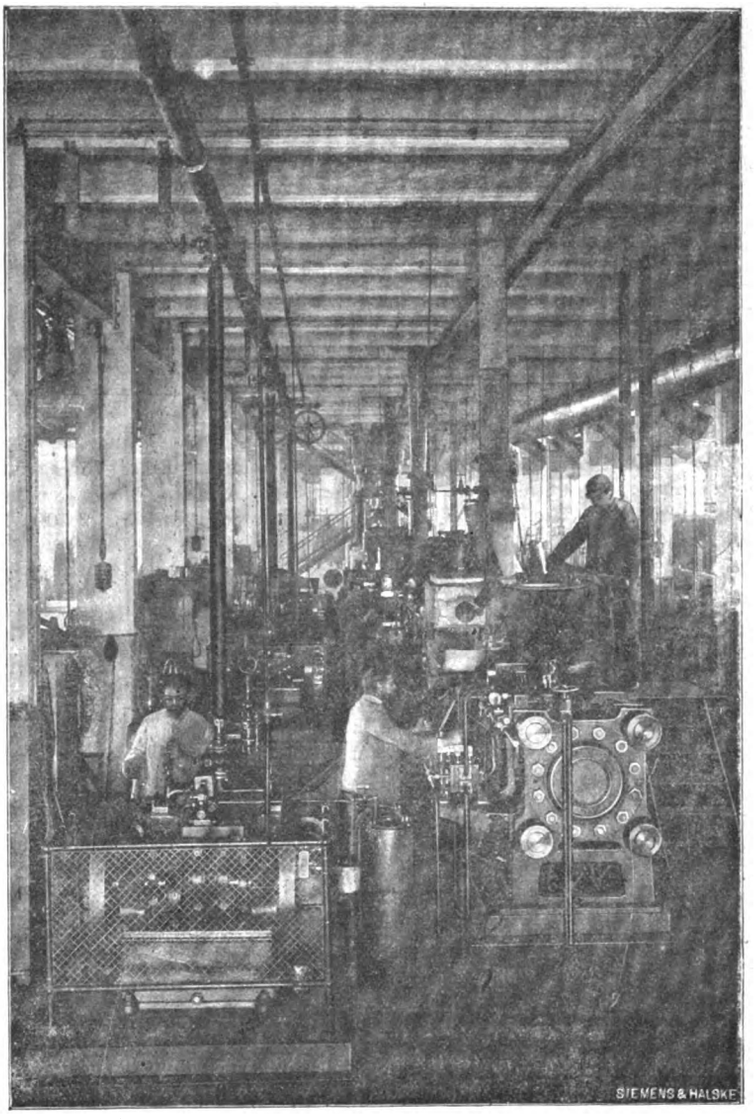

FIG 5.—Lead Press.

After the conductors have received a rubber or guttapercha casing, the further treatment depends on whether the wire is to be covered by spun, braided material or by a pressed mould of lead.

Manufacture of Spun and Braided Wires.—In the main building, as already mentioned, the manufacture of spun and braided wires goes on. Silk and cotton are used for this class of insulation. On spinning machines the dynamo wires are covered with the insulating material. In addition, braiding machines are used, which cover the wire with a hoselike casing, and work in the same manner as weaving machines. By a combination of spinning or braiding, in connection with impregnations of insulating material, many kinds of goods are produced.

Manufacture of Paper-Covered Cables.—The manufacture of telephone cables is carried on from the point of view that the capacity of the cable, even at great lengths, is to remain as low as possible. For this purpose an insulating material with the least dielectric constant is chosen. Dried paper has been found especially suitable, and the telephone wires are therefore covered with paper bands, wound in discs, and placed in the spinning machine, as shown in Fig. 8. After the single wires have been insulated with paper, they are spun on stranding machines to form multiple cables. Thereon the cables receive a protection against dampness by a covering of lead, as previously described, and are further protected by an armouring depending on the place where they are to be used.

Metal Foundry.—For Messrs. Siemens and Halske's own requirements a brass and copper foundry has been erected at the Nonnendamm flanking the cable works. The plant at present has a capacity of 800 to 1,600 tons per year. To begin with, four furnaces on the Piat-Baumann system and four crucible furnaces have been mounted. The moulding is done partly by hand and partly by machine. Next to the foundry are the drying-rooms. The casting takes place before the furnaces, and near the casting department are the sand and cleaning rooms. The different operations in the foundry take their course from east to west, while an extension of the foundry buildings would take a northerly direction.

(To be continued.)

HOYLAKE AND WEST KIRBY ELECTRICITY WORKS.

Hoylake and West Kirby are two residential districts favoured by Liverpool merchants, and are situated in Cheshire close to the mouth of the estuary of the River

Digitized by Google

Dee. Hoylake is best known for its famous golf links. There are no industries other than what is represented by the demands of the health-seeker. The district is a long narrow one, following the coast-line for about four miles, and hence best adapted for a high-pressure alternating system, as recommended by Mr. T. L. Miller, the consulting electrical engineer. The Local Government Board having sanctioned the spending of £30,000, a site for the station was selected at Hoylake close to the railway. To obtain foundations on the sand a bed of concrete 12in. thick was laid down, on which the works were built. For the chimney, which is 125ft. high, a satisfactory clay foundation was found. The boiler-house is 53ft. by 54ft., and is fitted with three Lancashire boilers made by Messrs. Tetlow, of Hollinwood. The engine-room is 33ft. wide and 50ft. long, and has ample room for considerable extension of the present plant. It contains three direct-coupled sets. The engines are compound, of 125 l.h.p. at 500 revolutions per minute, by Messrs. Belliss. The generators are Crompton-Brunton alternators, of 75 kw. at 2,400 volts, periodicity 50 ⁓. A motor-alternator is provided, designed on the alternating side for 2,400 volts and 14 amperes at 1,000 revolutions per minute, and on the direct-current side for 160 volts and 260 amperes. The alternator can be run as a synchronous motor to charge the cells or for excitation. At times of light load the direct-current side will act as a motor on the cells for supplying power to run the alternater. The switchboard is by Messrs. Cowans, of

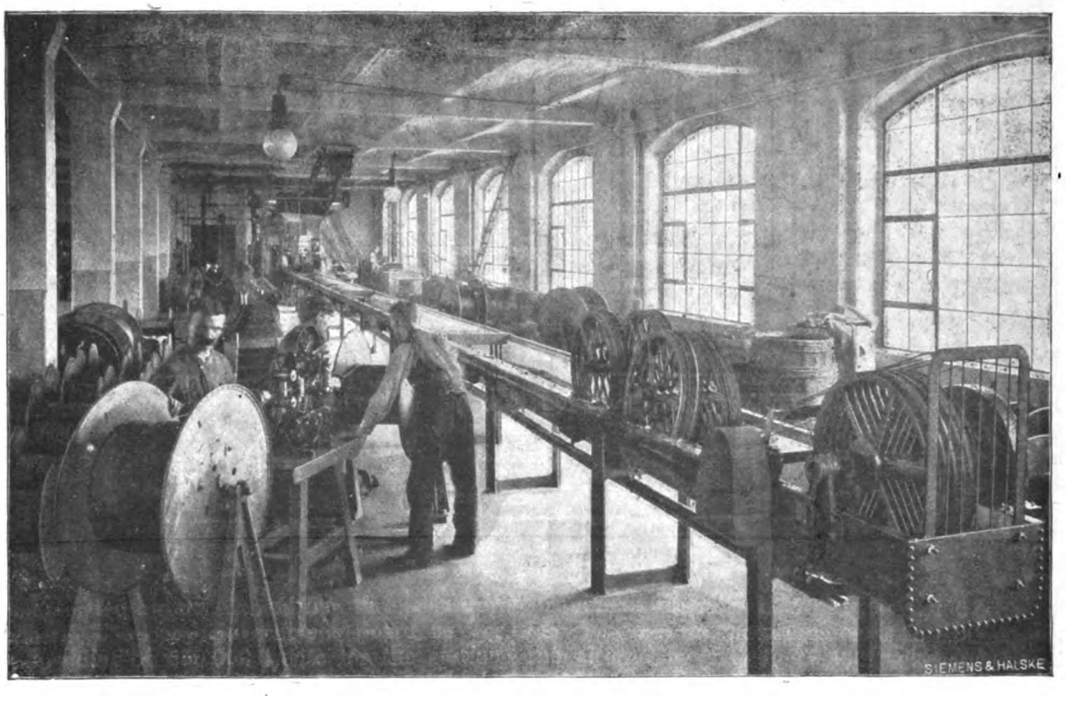

Fig. 7.—Guttapercha Press.

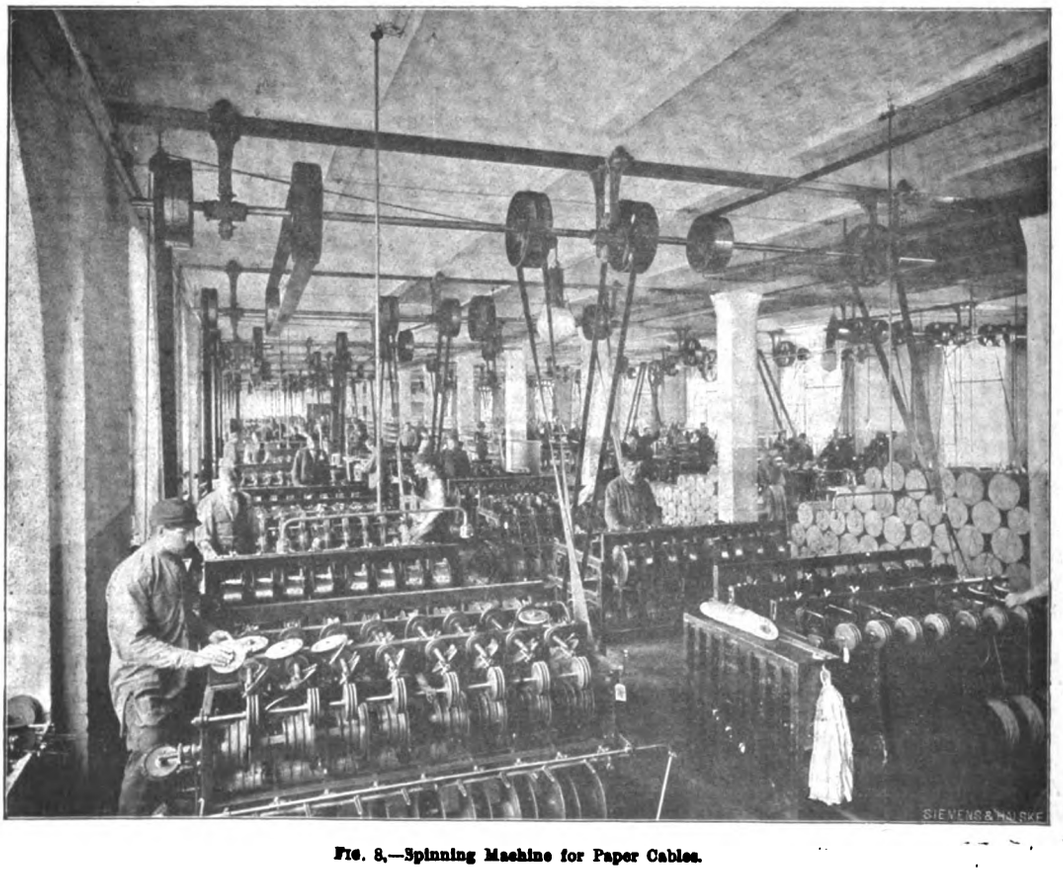

Fig. 8.—Spinning Machine for Paper Cables.

Digitized by Google

Salford. The battery is of the Chloride type, and consists of two sets, each of 60 cells, with a normal discharge rate of 100 amperes for five hours. The electrical engineer is Mr. E. Marples, who acted as clerk of the works; he was formerly of the Liverpool District Lighting Company. His assistant is Mr. E. H. Rhodes.

The works were formally opened last Saturday, June 8, by Mr. Wall, the chairman of the Urban District Council, and a luncheon was afterwards provided at the Royal Hotel, Hoylake. The usual toasts of "The King," "The Urban District Council and the Electric Lighting Undertaking," "The Consulting Engineer and the Architect," "The Contractors," and "The Press," gave opportunity to the chairman and the other speakers to express their satisfaction at the completion of the undertaking. The statement of the chairman with regard to the undertaking was particularly satisfactory. He said there were already applications for 6,000 8-c.p. lamps, which was not far short of the available supply, and the Local Government Board had been asked to sanction the expenditure of an additional £13,500, and it was expected that during the winter 10,000 lamps would be connected. The light that would be given would be "free from smell, free from dirt, and free from danger." Mr. Miller made the interesting statement that the new houses in the district were being wired for the electric light by the builders, who intended electricity to be the only method of lighting. Mr. Callender, as one of the contractors, congratulated the Council on being able to place extension orders before a wheel had been turned round. Dr. Smith, who was described as the pioneer of the district, reminded the company that "gas was not dead yet," and although he was associated with the gas company he did not fear the new light, for he always found that its rivalry with the electric light resulted in additional gas being used.

A few additional points of importance with reference to this latest electric supply undertaking may be added. The price is to be 7d. per unit for the first hour and 3d. for the second hour, the Wright system of charging being adopted. The price of gas is 3s. 9d. per 1,000 cubic feet. Street-lighting is to be undertaken at 9d. per lamp less than at present charged for gas. The supply is at 230 volts. There are two sub-stations, one at Hoylake and one at West Kirby; in other cases the transformers are in pits. This equipment has been supplied by Messrs. Cowans, of Salford. One of the sources of revenue will be the use of radiators in private houses. There will be no meter charges. Regulations for installation work have been drawn up by Mr. Miller. These do not call for any special remark, as they embody the usual rules as required for good wiring.

PERTH ELECTRICITY WORKS.

The Perth municipal electricity supply undertaking (the formal opening of which we described in our last issue) has been laid down on thoroughly up-to-date lines, and while the design of the plant does not introduce any outstanding novelties in design, the following short description of the plant will, we hope, prove of interest.

Perth is one of the numerous municipalities which have procured a provisional order more as a protection against the incursions of companies than from any great desire to instal the electric light. On obtaining the order the Commissioners received offers from no less than nine different companies, but on consideration of these tenders they decided upon putting down the works themselves. Mr. W. C. C. Hawtayne was chosen by the Commissioners as consulting engineer for the work, and the scheme which he recommended was a low-tension three-wire supply, with 460 volts across the outers. Contracts were placed as follows: buildings (local firms); boiler-house plant, Messrs. Babcock and Wilcox; pipework, Messrs. Babcock and Wilcox; surface-condensing plant, Messrs. J. H. Carruthers and Co., Glasgow; steam dynamos, Messrs. D. Bruce Peebles and Co.; storage batteries, the Electrical Power Storage Company, Limited; main switchboard, Messrs. Lowdon Bros. and Co., Dundee; overhead travelling crane, the Southgate Engineering Company, Limited; underground mains, etc., Callender's Cable and Construction Company, Limited; arc lamps and posts, Messrs. Lucy and Co., Limited; station lighting, Mr. Peter Campbell, Perth.

The total cost of the scheme has been about £30,000, which represents nearly £1 per head of population. The site chosen is on the "shore"—*i.e.*, on the banks of the River Tay. The ground was obtained on very reasonable terms, and the station is well situated as regards coaling facilities, while there is an ample supply of good water for feeding the boilers and for condensing purposes. The buildings have been erected to plans by Mr. McKillop, burgh surveyor, with the direction of Mr. Hawtayne. They are of red facing brick, and are designed to give plenty of room for extension of the lighting plant, and for the probable accommodation of traction plant. The principal dimensions are as follows: boiler-room, 115ft. by 42ft.; engine-room, 115ft. by 38ft.; accumulator-room, 48ft. by 31ft. There are also the testroom, workshop, store, lavatory, and offices, while above the latter there is a house for the charge engineer.

The chimney is of large proportions, being 150ft. high by 7ft. internal diameter. It is afterwards intended to erect a refuse destructor near the electricity works, and the chimney has been utilised to be used for both. The boiler-room at present contains three water-tube boilers of Babcock and Wilcox's well-known make. They are each rated for an evaporative duty of 6,000lb. per hour at a working pressure of 200lb. per square inch. The grates are of the ordinary pattern, and are hand-fired from the boiler-room floor. No superheaters are provided with the boilers, but as there is a large steam space provided and a very short and direct passage for the steam passing to the engines, there should be no difficulty in maintaining a supply of dry steam. The steam-piping is arranged on the simplest possible plan, the boilers being connected to a main header running along the wall, while the steam-piping to the engines are run right through the wall of the boiler-house to the engines, which are immediately on the other side of it. Only a single steam-pipe is taken to each engine, which we think preferable to the complicated arrangements of duplicate steam-pipes which used to be considered a *sine qua non* in an electricity central station. Isolating valves are provided for separating the boilers from each other. The steam-piping is of lap-welded mild steel with wrought-steel flanges, while the exhaust piping is of cast iron. Each boiler is fitted with a high-pressure injector, which is used to feed the boiler when the feed pumps are not in action. The latter comprise a direct-driven steam feed pump, capable of supplying 2,000 gallons per hour, and an electrically-driven pump for the same duty. The latter is a three-throw pump driven through spur gearing by a J. H. Holmes and Co.'s enclosed four-pole motor. This motor is arranged to work at two different speeds, either across the outers of the three-wire system or off the storage battery. A throw-over switch is provided for effecting this. The feed water is taken first from the River Tay to a wrought-iron feed-water tank under the boiler-house floor capable of holding 2,000 gallons. From this tank it passes through the pumps and thence through a Green's economiser to the boilers. Duplicate feed pipes are laid from the two feed pumps to the boilers.

The engine-house is finished off inside with a lining of brown enamelled tiles to a height of 5ft. from the floor; an overhead hand-power crane (10 tons) runs the whole length of the engine-house. The steam dynamos at present installed are three in number, and consist of two sets each of 200 kw. output, and a smaller set of 75 kw. output. The engines are of Willans and Robinson's make, and are direct coupled to Bruce Peebles's multipolar dynamos. The larger dynamos run at 350 revolutions per minute, while the 75-kw. set runs at 460 revolutions per minute. The voltage of all machines can be varied from 460 to 550 volts. All the dynamos are compound wound, with a view to their being used for traction purposes. A plug on the side of the frame is provided for short-circuiting the series coils when these are not required. The engines are compound, and are all fitted with Willans

Digitized by Google

and Robinson's patent steam-actuated variable cut-off gear, which provide for altering the cut-off to suit varying conditions of load, thus conducing to increased economy in working. The engines exhaust either into the air or into a surface condenser, which is placed at one end of the boiler-house. This condenser is capable of dealing with 18,000lb. of exhaust steam per hour. It is of the ordinary marine pattern, with direct steam-driven reciprocating circulating pump underneath the condenser body. The circulating water is obtained from the Tay. The switchboard is of the usual three-wire type, with circular pattern accumulator regulating switches. Provision is made for charging the regulating cells of the battery apart from the other cells. Duplicate fuses are provided for all feeder circuits, while the dynamos are protected by automatic cut-outs. Ample provision has been made for future extension, while the main generator switches are made of the throw-over pattern, one side for lighting and the other side for traction. For battery charging and balancing a booster-balancer combination has been laid down. This consists of four machines in line, all on the same spindle and bed-plate. The boosters are capable of giving out 175 amperes at 120 volts, while the motors (which also act as balancers) run at 250 volts, and take 100 amperes at full load. The whole combination runs at 900 revolutions per minute.

The storage battery is in two halves, one on each side of the three-wire system The cells have an output of 600 ampere-hours, discharging at 200 amperes for three hours. There are 135 cells in each battery, 29 of which are regulating cells. The total output of the battery is rated at 517,800 watt-hours. The connections between the different tiers and sections of the battery, and between the regulating cells and the back of the switchboard, are of solid bare copper rod, which is run on porcelain insulators and protected by enamel acid-proof paint.

We now come to the street mains, which are all of the Callender Company's vulcanised bitumen type. There are four concentric feeders laid, three double and one triple. They are lead covered, armoured, braided, and laid direct in the ground. On certain parts of the system porcelain tubes have been laid for drawing-in additional feeders or extending those already laid. The distributing cables are laid on the solid system, and consist of three separate cables run in solid with bitumen in a wooden trough. Up to the present 5,700 yards of feeders and pilot wires and 7,250 yards of distributors have been laid. There are in all 67 arc lamps of 1,000 nominal candle-power of the Crompton-Pochin enclosed long-burning type, and they are run four in series across the outers. On each arc-lamp pillar are placed two brackets supporting two 32 c.p. incandescent lamps, while about 84 of the existing gas-lamp pillars are being adapted for incandescent lamps. About 5,200 yards of cable have been laid for the arc lighting, while the incandescent lamps are controlled from four different points, about 2,200 yards of cable having been laid for this purpose. Up to date about 20,000 8-c.p. lamps (equivalent) are wired in the town, exclusive of the public lighting, so that good progress is being made.

Both lighting and power are charged on the maximum demand system, the charges being 7d. and 3d. for lighting purposes, and 7d. and 1½d. for power. It should have been said that no manholes are used for connecting the feeders to the distributors. These connections are all brought up into section pillars, where the necessary connections are taken off 'bus bars mounted on marble or porcelain slabs. No fuses are placed in these pillars. The arc-lamp posts cannot be described as being very artistic in design, but we have no doubt the citizens of Perth will in time become used to their somewhat harsh outlines. Judging from the good start made by the Perth undertaking, it should become a commercial success in a comparatively short time, and with this hope expressed we will close our description of the undertaking, which has necessarily been a short one

---

Crewe.—The Town Council have decided to oppose the application of the British Electric Traction Company for an order to construct electric railways in Crewe and Haslingden, on the ground that an order should be granted to the Corporation in preference to outsiders.

THE CONSUMER'S DEPARTMENT OF A CENTRAL STATION.

(Concluded from page 686.)

Before bringing this short series of articles to a conclusion, it would, perhaps, be as well to write a few lines with reference to the various complaints which are received from consumers, and also about the disputes which are likely to arise from time to time.

However well a system of supply might have been designed, and no matter how much care is exercised in order to ensure the consumers having a full and uniform voltage, there are almost certain to be some individuals who will find fault and grumble about their light for some reason or another. It might be mentioned, in passing, that, as a rule, the notifications which are received at the station upon matters of this kind, whether they be in the form of a letter or whether the consumer honours the engineer with a personal call, are by no means as polite as one might wish them to be, and very frequently the assistant to whose lot falls the investigation of these matters has an experience very far removed from being pleasant. Let us suppose that a consumer has reason (imaginary or otherwise) to find fault with the light he is getting. He generally sends off a letter to the works in which he says that his lamps do not give as much light as he would get from a farthing candle. The author does not know whether the farthing candle is a standard of light according to the views of the ordinary individual, but it has been his experience to find that it is very often looked upon as a basis for comparison. To continue, however, this letter generally contains a threat to discontinue the use of the electric light unless something is immediately done to put matters right. Not only does he say that he himself will stop using it, but he will advise a great number of his friends who are about to put in an installation to abandon the idea, as the electric light is a failure, etc. No doubt the gentleman thinks in his own mind that by assuming this attitude he will cause the engineer to tremble in his shoes, and think that his undertaking is about to receive its death-blow. Little does the irate gentleman think that communications written in this strain are generally received with a quiet smile on the part of the engineer. Do not let it be thought for one moment that the author is disposed to take no notice of complaints of this kind, for it is his opinion that every complaint, however trivial it might appear to be, should receive proper attention, and if there is found to be no cause for complaint, it will not be a difficult matter to demonstrate the fact to the consumer.

After a considerable experience in this department of station work, the author rather enjoyed the prospect of having to deal with a gentleman who would write a letter similar to the one described above, as the fact of him comparing the light given by his lamps to that of a farthing candle at once demonstrated that he was not particularly truthful, which in itself was something to be going on with. The first thing to do in a case of this kind is to go round and visit the consumer at the time of heavy load, or at the time during which the light is alleged to be bad. After trying to calm the gentleman down as far as possible, the voltage at the service mains should be taken. If the voltmeter shows that the pressure is up to that declared by the undertakers, or within the limit allowed by the Board of Trade, and in spite of this the lamps do not give a proper light, it is obvious that the cause must be looked for upon the premises. In almost nine cases out of ten the fault will be found in the lamps themselves, the consumer having burnt them so long and not having the sense to see that the blackened globe was absorbing most of the light. A very good way of impressing this condition of the lamps upon the consumer is to lay one upon a sheet of white paper, when the strong contrast will at once be seen. It seems impossible to make the consumer understand that it is not always advisable to burn a lamp until the filament actually breaks. If the lamps themselves appear to be in fairly good condition, all main connections to switches and fuses should be carefully

Digitized by Google

examined to see whether proper contact is being made. The meter leads should also be looked to, as these are very liable to work loose at the terminals, as owing to the situations in which meters are generally fixed they are very often subjected to a certain amount of vibration. In some cases it may be found that the consumer has been increasing the load on his mains, either by changing the candle-power of his lamp, or some enterprising plumber might have carried out some extensions and tapped on to a main which was already fully loaded. If the consumer states that the light is all right at the time of the inspector's visit, but that its behaviour is very erratic during various times of the day, the only thing to do is to fix a recording voltmeter on the premises for a few days and obtain a record of the pressure throughout the 24 hours. This instrument should always be connected on to the service mains, and not on any account should it be connected to any portion of the consumer's apparatus, such as the main switch or fuse. If, upon taking this record, the voltage is found to be lower than it should be, and the system of supply is a three-wire one, the voltmeter should be connected for a few days on to the other side of the system. If this particular consumer is supplied from two service mains only, as would be the case if it was only a small installation, the instrument should be removed and fixed in another consumer's place whose supply is taken from the other side of the middle wire, and it should be as near as possible to the point on the mains at which the first records were taken. If the records obtained on this side of the network show the pressure to be as much above the proper value as the previous ones were below it, the cause of the bad light in the first case is owing to the uneven balancing on the mains, and immediate steps should be taken to rearrange the balancing of that particular street; and when this has been done the light will be found to be all right, and the consumer made happy once more. If, however, both records are bad, it will probably be found that the mains are overloaded, and the complaint, together with the records which have been taken, should be handed over to the mains engineer for further investigation, as this work is outside the province of the installation department. When a consumer sends round to the station to say that his lights are out, someone ought to be sent immediately, for there is nothing worse for an undertaking than allowing such complaints to be neglected, and it is most important that the consumers should have every consideration shown to them, and be put to as little inconvenience as possible. It is well worth while, in the case of a large undertaking, for someone employed in the installation department to be kept at the station after the usual office hours, say until 11 o'clock, so as to be in readiness to attend to any complaints which might come in. It is very often left for the shift engineer to send someone out of the station, but this is not an advisable course to adopt, as very often, especially during the winter months, a suitable man cannot be spared. It would only be necessary to keep a youth for this purpose, and it could easily be arranged for him to take duty in turns with one of the other boys in the department.

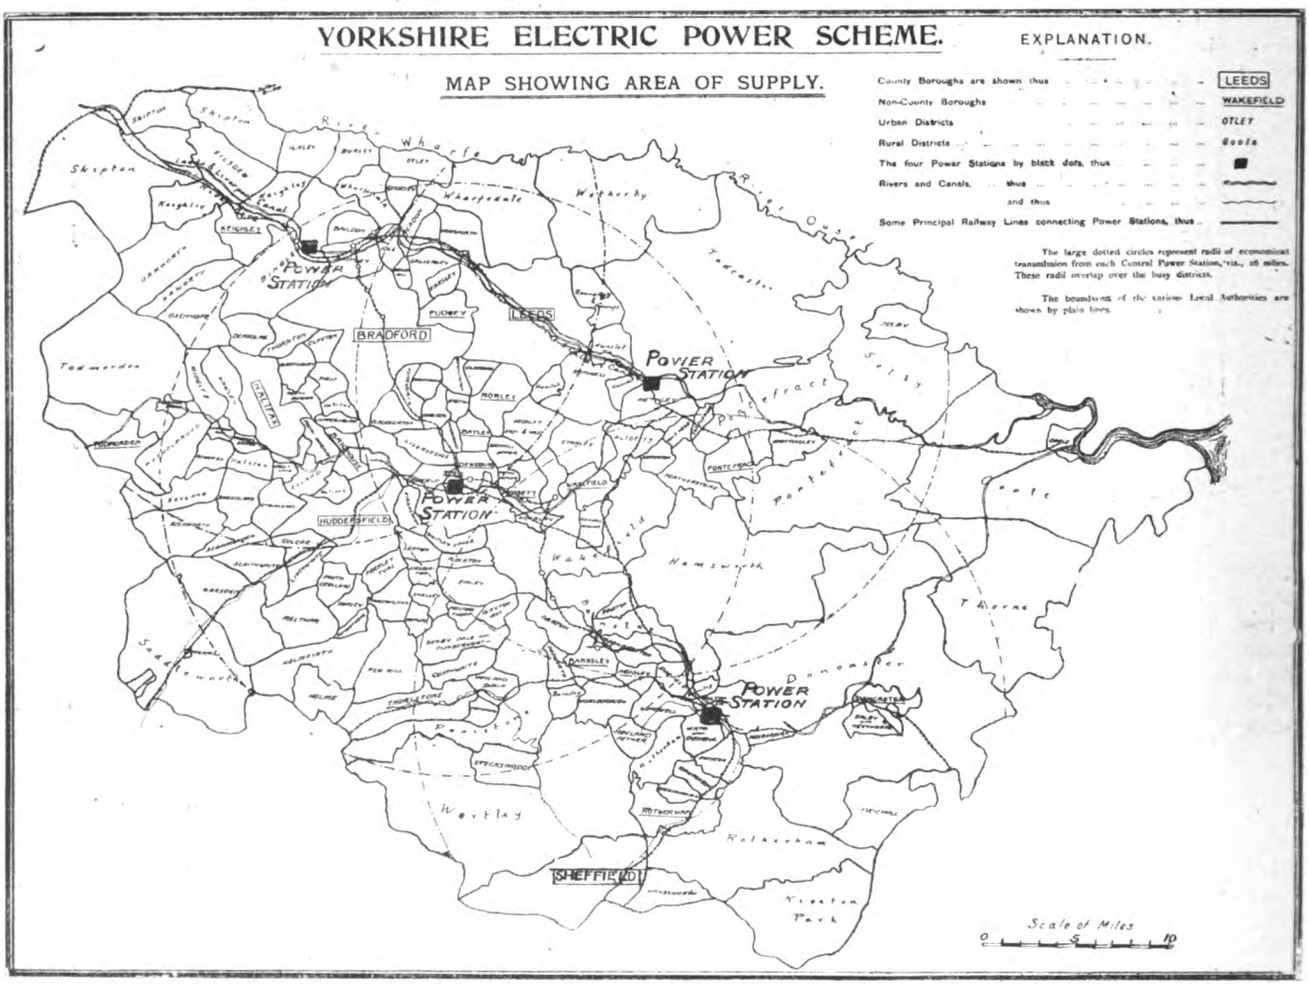
It is the general custom to render the accounts to the consumers once a quarter, but the meters should be read every month, and then any meter which has stopped, or appears to be recording incorrectly, can be changed at once, and if it has actually stopped, the estimated consumption will only have to be obtained for a month, instead of for a whole quarter, as would be the case were the meters only read for the purpose of charging. The monthly readings should be compared roughly with the readings during the corresponding month of the previous year, and if any great difference in the consumption be observed, the matter should be looked into to see whether the meter has not been read properly or whether it is out of order. Every quarter is sure to bring in a considerable amount of work for the installation department, as there are almost certain to be some people who will dispute their accounts, and these people will have to be seen, and if they cannot be convinced that everything is right, the offending meter will have to be removed for testing, the consumer bearing the expense if the meter is found to be inaccurate. It would be a good thing if meters which are disputed could be tested on the premises under the exact working conditions, but it is impossible to do this with any degree of accuracy owing to the unsteadiness of the current if taken off the ordinary supply mains. In the event of a meter stopping, the simplest way to do, if one can obtain the consent of the consumer, is to render the account on the readings during the corresponding period of the previous year. It is not often, however, that this arrangement can be made, as the customer will invariably say that he has not used anything like the same amount of light that quarter. Whatever arrangement is made, however, it should be done with the consumer himself, or with some person duly authorised by him, as if an estimate is arrived at by the aid of anyone without authority, and the account is rendered accordingly, the chances are that the account will not be agreed to. After some experience in this department, the inspector will be able to estimate an account pretty well by looking over a building, and taking into consideration the class of business which is carried on, he will be able to judge as to what the probable hours of burning will be, and knowing the number of lamps installed, the consumption in Board of Trade units can easily be arrived at. Of course, to some extent, one is at the mercy of the consumer, but so long as electricity meters will get out of order we must be prepared to stand to lose a little, and it is only human nature on the part of the customer to make his bill as little as possible. In bringing these articles to a close, the author hopes that some of the points mentioned will be of use to some of the junior assistants in central stations.

THE YORKSHIRE ELECTRIC POWER BILLS.

The last of this session's Power Bills has passed through committee, and it is a matter for congratulation that only in the case of rival schemes has any Bill been rejected this year. The Yorkshire electric power scheme is by far the most gigantic and important of any promoted in this session of Parliament, not only on account of the large area which it proposes to serve—1,860 square miles—but mainly because of the vast importance of the district as one of the biggest manufacturing centres in the United Kingdom. The measure embraces practically the whole of the West Riding of Yorkshire, in which the collieries alone have an annual output of 15 million tons of coal. The coalfields, too, are rapidly being developed, and it is thought that the supply of electric power in this district will be of the greatest value for the new boring and sinking operations. When the Bill came before the Select Committee of the House of Commons presided over by Sir Wm. Houldsworth, it was opposed for the first few days by a competing scheme—the South Yorkshire Electric Power Bill—but towards the end the proceedings were greatly simplified by an agreement between the two sets of promoters, the main provision of which is that three of the directors of the South Yorkshire Company shall join the Board of the successful Yorkshire Company. The Bill promoted by the former company was accordingly withdrawn. The Yorkshire scheme is promoted by the principal representatives of a countryside teeming with manufacturing industries, and the list of 63 persons who form the syndicate include well-known names such as Armitage, Blackhouse, Baynes, Brotherton, Crawshay, Fox, Green, and Holliday. Among the industries represented we may mention engineering, cloth manufacturing, curriers, timber, mining, coal, etc. Some 13 of the 63 firms mentioned employ about 55,000 odd hands and use machinery of just upon 42,000 h.p. So there can be no fear as regards consumers. The maximum charges which the company are entitled to enforce for supply of energy are: for the first 5,000 units consumed in any quarter, 3d. per unit; between 5,000 and 10,000, 2¾d. per unit; between 10,000 and 20,000, 2½d. per unit, etc. Under this measure it is proposed to have four generating stations—one at Methley, one at Wath, one at Thornhill, and one at Bingley—and a radius of 16 miles from each of these places practically covers the whole area. There are in this area five county boroughs, 13 ordinary boroughs,

Digitized by Google

140 urban and rural districts, and these only administer electricity to 130 miles out of 1,800 miles. At the present time only a small fraction of these authorities provide a supply of electricity, and such supply as there is is used practically only for tramways and lighting. It must be remembered, however, that some 11 of the larger boroughs have got works either commenced or in operation, while about 16 hold provisional orders. The capital of the company will be £2,000,000, of which £10,000 has already been raised for engineering purposes, etc. On the withdrawal of the South Yorkshire Bill, the chief opponents to the other scheme were the Corporations of Leeds, Bradford, Sheffield, and Barnsley, who strongly objected to having the areas under their jurisdiction included in the area of supply, and also protested against interference with their roads by the company. The Corporation of Leeds stated that they had spent £600,000 on their electric works, and were now incurring large additional expenditure. They added that they were able and



willing to meet all the requirements of their city so far as the supply of electricity was concerned, and they thought it unfair that a profit-making company should be allowed to enter into competition with them. Similar views were expressed by the other petitioning corporations. A great mass of evidence, expert and otherwise, was called on both sides, and after an enquiry lasting for some days the chairman announced that the committee had decided that the preamble of the Yorkshire Bill was proved. With regard to wayleaves, they would not exclude Bradford, Leeds, or Sheffield, but they desired to express the opinion that they would like to see a prohibited area in each of these places agreed upon. With regard to the railways and canals, they passed the Bill as it stood. After this intimation the three county boroughs mentioned by the chairman gave notice that they would withdraw from the enquiry altogether, reserving themselves to oppose in the House of Lords. The question of prohibitive areas was then considered by the committee, with the result that the chairman announced that in the case of Huddersfield, Halifax, and Barnsley prohibitive areas had been agreed upon by the parties, and with regard to Sheffield, Leeds, and Bradford the committee wanted from the promoters a clause undertaking that there should be a prohibitive area of a mile from some specified place. In accordance with this direction a clause was agreed to by which it is provided that "the company shall not, without the consent in writing of the local authority, break up any street or allow any electrical line or other works along any streets in the respective cities of Bradford, Leeds, or Sheffield which is included within a certain specified area delineated on the plans." In respect of Leeds and Bradford, the prohibited area constitutes a mile radius from the municipal buildings. In the case of Sheffield, however, the density of the population makes an absolute circle impracticable, and the promoters have accordingly drawn a circle with a radius of 1½ miles from the Jubilee Obelisk. By this arrangement a sparsely-populated district, which would otherwise have been included in the mile circle, has been left out of the prohibited area, and, as was pointed out before the committee, the promoters will be able to join up with the Derbyshire and Nottinghamshire Power Company without touching the prohibited area of Sheffield. With these additions and alterations the Bill will be reported for third reading. The engineers to the Yorkshire scheme are Messrs. Gibbings and Baker, of London and Bradford; and the parliamentary agents Messrs. Rees and Frere, of Westminster.

WIRELESS TELEGRAPHY AT RATHLIN ISLAND AND THE SKERRIES.

Some interesting experiments are now being made in connection with induction telegraphy between the mainland, North of Ireland, and Rathlin Island, on which Lloyd's have a signalling station. The experiments have been going on practically the whole of the year, but the system was officially inaugurated only on Friday week. The two points actually in communication are the Bally-

Digitized by Google

castle Post Office and Lloyd's signalling station. As is the case with other installations of this induction telegraphy, the Post Office, we are informed, have erected two parallel lines. It will be seen from the accompanying sketch (Fig. 1) that the first of these runs between Ballycastle and Murtough Bay on the mainland. The other wire

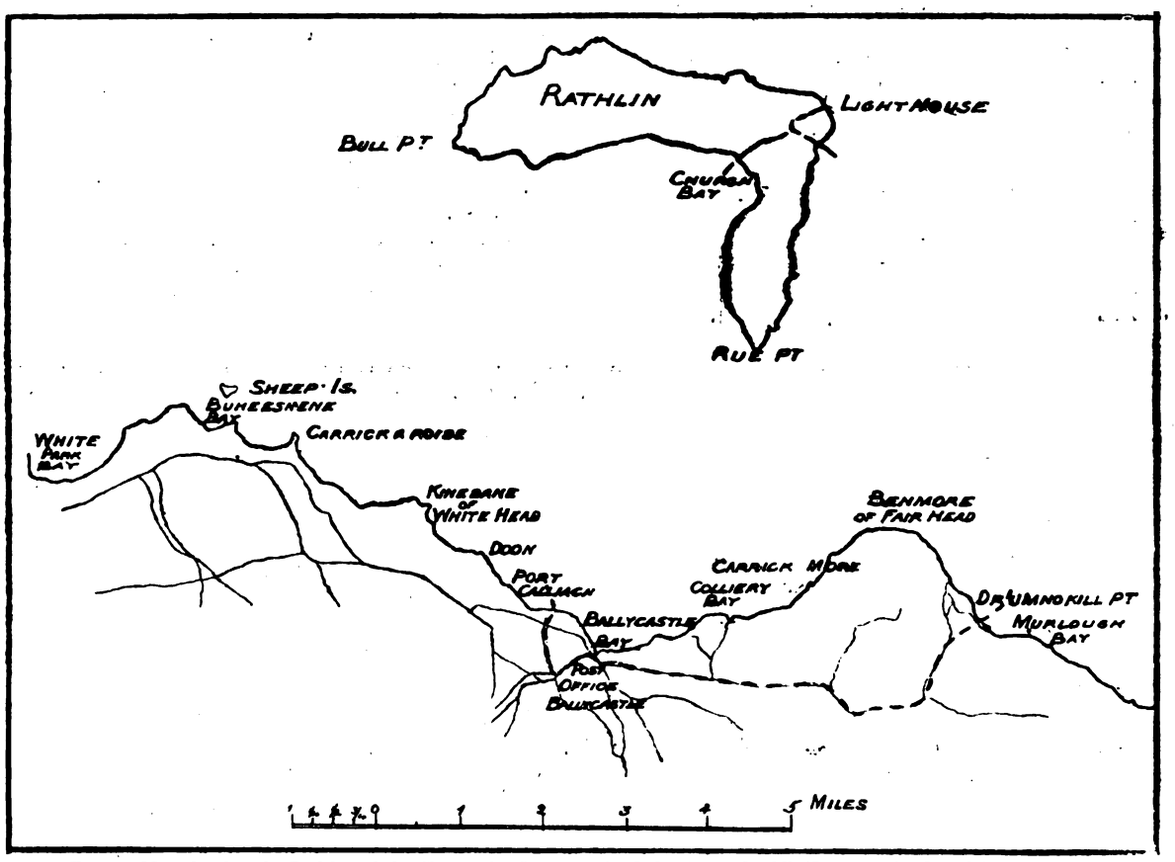


FIG. 1.—Map showing the Position of the Circuits for Signalling by Induction to Rathlin Island. The dotted lines represent the overhead telegraph wires which are earthed at either end in the sea.

connects Church Bay on Rathlin Island with the north-east corner of the island. The ends of each of these wires terminate in the sea. The wire on the island is about 1½ miles in length, while the length of that erected on the mainland is just about six miles. The average width between the parallel portions of the wires may be taken to be 6½ miles. The signalling current is obtained by means of a small Cuttriss motor, which gives a current with a frequency of about 300 complete periods per second. This current is interrupted by means of the ordinary telegraph key using the Morse code. At present the authorities are working with a maximum of two amperes in each of the primary circuits. At the receiving station the operator has only to listen at a telephone in the receiving circuit. We understand that the Post Office have not got a successful calling apparatus yet. Experiments are, however, being carried on with apparatus designed by Prof. Lodge and Mr. Sydney Evershed, but no final decision has up to the present been come to. As it is now, the operators have to listen at fixed intervals for the signals. These intervals in the ordinary way would be half an hour. The experiments are said to have been most successful, and the system is now open for public use. The system of induction telegraphy was first experimented with by Sir Wm. H. Preece in 1894, across Loch Ness, in the Highlands, but the installation in question has been carried out under

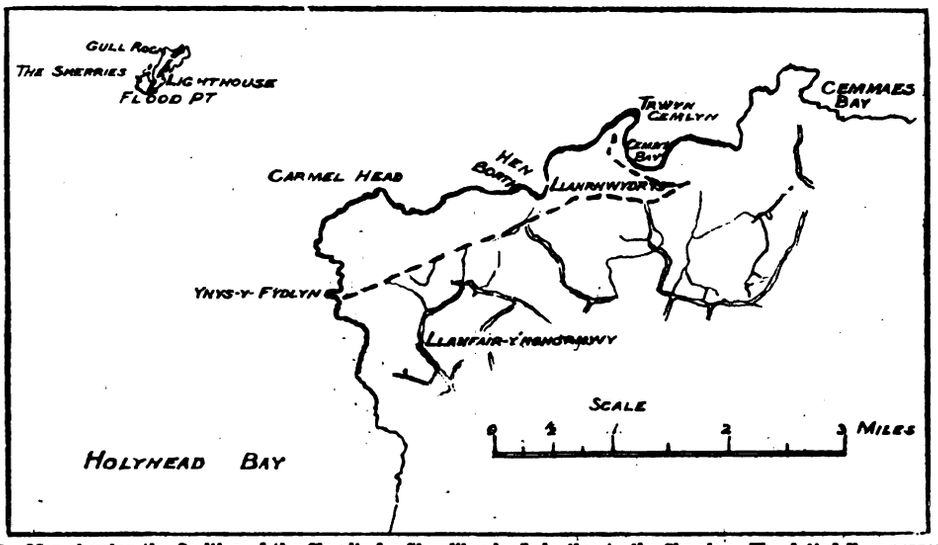

FIG. 2.—Map showing the Position of the Circuits for Signalling by Induction to the Skerries. The dotted lines represent the overhead telegraph wires which are earthed at either end in the sea.

the supervision of Mr. Thomas Patterson, the sectional engineer of the district. Other gentlemen who have worked in connection with the same are Mr. J. Walby, superintendent engineer for the North of Ireland, and Mr. Davies, Prof. Lodge's principal assistant.

We are also informed that further experiments have resulted in the establishment of wireless telephonic

Digitized by Google

communication between the Skerries and the mainland of Anglesey, as shown in Fig. 2. The lighthouse on the Skerries was wanted to be in communication with the coastguard station at Cemlyn, which is connected with the Post Office system. A wire 750 yards in length was erected along the Skerries, and on the mainland a wire of 3½ miles from a point opposite the Skerries to Cemlyn. Each line terminates by an earth-plate in the sea. The average distance between the parallel portions of the two wires is 2·8. The conditions of this communication, with these exceptions, are practically the same as those in the case of Rathlin Island, and a good service of telephonic communication is being well maintained.

A 500-KW. PARSONS STEAM-TURBINE TRIAL.

We have received a copy of a most interesting report by Prof. J. A. Ewing of a series of trials made by him on a turbo-alternator at the works of the Cambridge Supply

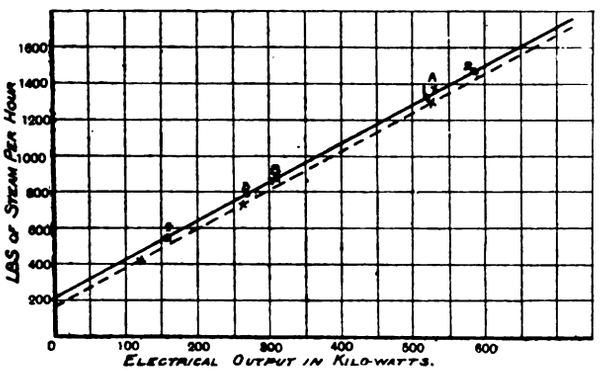

FIG. 1.—Two Curves of Total Steam Consumption.

Company. This machine was supplied by Messrs. C. A. Parsons and Co., and was erected in January, 1900. It has been in regular use since then on the station load, and the object of the test was to see if any appreciable falling off in the efficiency of the steam-turbine would be found after a year's work. The 500-kw. alternator on which the test was made is driven by a compound turbine of the parallel-flow type, running at about 2,700 revolutions per minute and governed electrically to give constant volts, with its shaft directly coupled to the armature of a four-pole alternator generating 250 amperes at

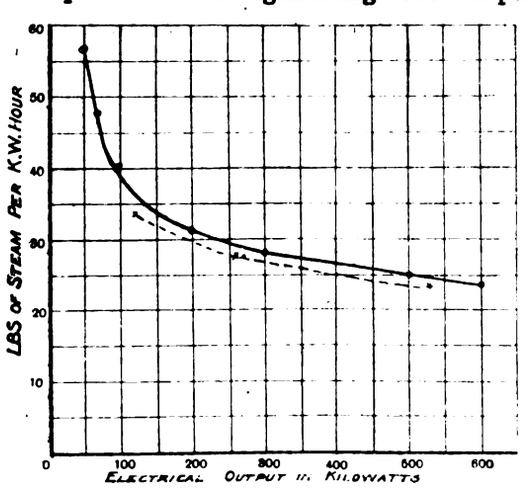

FIG. 2.—Curves of Steam per KW.-Hour. The full lines in each case are from Prof. Ewing's tests, and the dotted lines from tests taken a year before, when auxiliary plant was not driven by the turbine.

2,000 volts. The exciter armature is on a prolongation of the same shaft. Steam was supplied at 150lb. per square inch from a pair of Lancashire boilers, through about 140ft. of a steam-pipe, for the most part 6in. in diameter. The steam was not superheated, and there was no separator, but water which collected in a pocket under a vertical limb of the steam-pipe leading to the engine was from time to time blown off. This, however, was insufficient to keep the steam dry, for the velocity of steam in the pipe was too great to allow much of the moisture to be deposited in the pocket. Evidence that the steam was, in fact, wet on admission to the turbine was given when an indicator was applied to record the variation of pressure in each of the successive blasts by which the steam was admitted. This wetness would, of course, affect unfavourably the results of the tests. The turbine is furnished with a surface condenser, and drives its own air-pump and circulating pump (the latter lifting water 12ft.), by means of a shaft carrying a screw wheel which is driven by a worm on the main turbine shaft. The measured consumption of steam, therefore, includes what is required to drive these auxiliaries. The discharge from the air-pump was delivered, for the purpose of the test, through a two-way valve into tanks which were filled alternately. The discharge into each was continued until the tank was filled up to an overflow lip in a narrow neck, and the valve was then thrown over to fill the other tank, any overflow from the lip being collected in a can and emptied into the other tank. The time at which each tank in turn was filled was noted to the nearest second, and the times were taken continuously from tank to tank during each run in the trials.

The output of the alternator was measured on a Kelvin watt-balance, which was recalibrated after the trial in order to get exact results. Readings were also taken on other instruments to serve as additional check. The artificial loads used on the trial consisted of two iron plates immersed in the River Cam. By altering the depth of the one plate the load was varied from 586 kw., which was one-sixth overload, down to zero. The two curves which we reproduce herewith record graphically the results obtained. The actual figures of the trials are given in the accompanying table:

No. of trial.	1.	2.	3.	4.	5.
Electrical output in kw.	518	586	273½	160½	—
Volts at terminals of generator	2,100	2,150	2,250	2,290	2,280
Speed in revolutions per minute	2,670	2,740	2,630	2,590	2,580
Air-pump discharge, lbs. per hour	12,970	14,320	7,730	5,320	1,850
Air-pump discharge, lbs. per kw. per hour	25·0	24·4	28·3	33·1	—
Pressure at stop-valve, lbs. per square inch	148	145	151	151	121
Vacuum in condenser, inches	27·8	27·9	28·2	28·3	28·3
Vacuum in turbine cylinder, inches	25·7	25·4	27·2	27·8	28·1
Temperature of air-pump discharge, deg. F.	74	76	57½	56	54
Temperature of circulating water, inlet deg. F.	40	40	38	39	36
Temperature of circulating water, outlet deg. F.	71	72½	60	57	46
Barometer, inches	—	—	29·93	—	—

These figures are compared on the curves with others obtained at Newcastle-on-Tyne, when the air and circulating pumps were not in use. It will be seen that the difference between the two is practically what would be expected from this fact. Prof. J. A. Ewing concludes by expressing his opinion that the results of the trials show that no deterioration due to wear has taken place. In a note at the conclusion of the report the makers refer to the fact that the type of turbines has been improved since the Cambridge machine was made. They give particulars of two turbo-alternators, also of 500 kw., in which lower steam consumptions were obtained. Thus, in the one supplied to the Cheltenham Corporation, and tested by Mr. Hamilton Kilgour, the steam consumption was only 21·7lb. per kilowatt-hour. A Scarborough, tested by Mr. F. G. Holden, took 22·7lb. of steam per kilowatt-hour. It was running at a speed of 2,400 revolutions per minute, whereas the Cheltenham machine was driven at 3,000 revolutions per minute. In neither case was the steam superheated. These figures are most interesting as showing how economical these steam-turbines are, and that they do not lose their good qualities in consequence of wear.

It may interest our readers to hear that Messrs. Parsons and Co. have recently taken an order for a turbine engine for delivery to Milan capable of giving power to a 2,000-kw. dynamo being built by Messrs. Brown, Boveri, and Co., of Baden, Switzerland. The contracted time for

Digitized by Google

delivery is 10 weeks from receipt of order. It is good news to find such large machines being ordered for export.

ATKINSON DEAD-BEAT AMMETERS AND VOLTMETERS.

Through the kindness of Messrs. L. B. and C. W. Atkinson, we are able to give a short description of a new type of ammeter and voltmeter which is now being manufactured in large quantities at the Atkinson Testing Works, Cardiff. This type of instrument, of which Fig. 1 represents the ammeter and Fig. 2 the voltmeter, is designed with the special object of providing instruments to be used in power distribution schemes. It is justly pointed out by the makers that in all power works in which electric motors are used, it is of importance that the operators should know how much current is being taken by each motor, as often a slight alteration in the arrangements will result in a considerable saving of power. In far too many instances electric motors are installed and started to work without even a preliminary test being made of how much current the motors are taking. If, then, the load be more than the motor is designed for, trouble ensues, and the whole of the blame is put down to the design of the motor, which is most unjust. The moving part of these ammeters and voltmeters is illustrated in Fig. 1. It consists practically of a hydrometer floating in a sealed tube. The liquid used is a saturated solution of a certain salt, which has a constant density at all temperatures. By having a few crystals in the liquid, the makers ensure that the solution shall always be a saturated one independent of the temperature. Up the middle of the hydrometer is placed a thin iron wire, and this is acted upon by a solenoid placed higher up the tube. The illustrations which we give show how the divisions vary at different parts of the scale, and that an exceedingly open scale can be obtained at that part of the range where it is required. The great advantage claimed for this type of construction is that by using a hydrometer as the moving part, all the costly and delicate jewelled pivots required in the usual types of instrument are avoided. Also the movement of the indicator is exceedingly dead-beat, as the passage of the liquid round the bulb of the hydrometer speedily damps down any tendency to oscillation when there are sudden variations in either the current or voltage which is being measured by the instrument. The claim is also made on the information sent to us that the instruments are not affected by external magnetic fields, but on this point we should like to see some experiments made before endorsing the claim. Reverting to the hydrometer, the float is made to fit the outer tube fairly closely, but three small projections on the bulb are made which prevent it from adhering to the side of the glass tube. The great advantage of the instrument from the commercial point of view is that it is exceedingly simple, and can hence be manufactured at exceedingly low rates without prejudicing its accuracy. We understand that special rules have been laid down for the manufacture of these instruments in large quantities, and from the list prices which we have seen they should command a ready sale. Although it might seem rather extravagant to put an ammeter on each motor in a workshop, yet the introduction of such an instrument would frequently save more than its own cost in a year in keeping down the repairs to the motor only; while if the instrument be read frequently, the saving in the current required will exceed many times the first cost of the instrument used to indicate the consumption at any instant. The general appearance of the ammeters and voltmeters is exceedingly neat and workmanlike, and the connections for the ammeters can be made on the front or the back of the switchboard at the wish of the purchaser. On each scale an indicator is provided, which can be fixed opposite the correct current or voltage at which the circuit should be worked, so that the operator can see at once if the normal conditions are varied.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street London, E C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 month
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered price 8s. 6d.

AUTOMOBILISM.

Quite recently the long-distance race for mechanical motors on common roads was extensively noticed in both the political and the technical Press. It seemed to strike none of the reporters that such a race was calculated rather to retard than advance the general introduction of such motors. Neither the man who desires to replace his carriage horses, nor the man who would replace the horses of his drays and wagons, wants to use a forty or fifty horse-power motor or run at a speed of forty or fifty miles an hour. The Automobile Club of this country is doing excellent work among our local legislators in showing the completeness of control the driver has over his vehicle, and in striving for the relaxation of a too rigid rule relating to "miles per hour." We have always striven to show that there are at least two ways of looking at most questions. In this there is the view of the driver and passengers on the vehicle, while, on the other hand, we get the view of all other users of the roads. The acme of civilisation is that every man should have all the freedom compatible with the least interference with the freedom of all other men. A man's actions may well be likened to the motion of a molecule. Each gets interfered with in every direction, yet under certain restrictions is perfectly free over a somewhat undefinable path. Using this illustration in regard to automobile travelling, the moral to be evolved is that the automobilist should have as few restrictions placed upon him as possible, and these only such as prevent interference with the freedom of the rest of the community. If the automobilist likes to take his machine into the Sahara and commit suicide by fast driving, who will say him nay; and why should anyone say him nay here provided his recklessness is harmless to all other parties? In a thickly-populated country, however, it is impossible to permit absolute freedom of driving, yet too great a strictness is just as bad in one way as too great laxity is in another. There is a point made much of by the opponents of automobilism—the frightening of horses. We do not think this should be allowed a moment's consideration. Horses *must* be taught by their owners to meet or pass any kind of vehicle. The same clamour was raised upon the introduction of railways, of traction engines, and even of reaping and mowing machines. But even if the horse be unteachable—which it is not—the introduction of mechanically-propelled vehicles generally, means the gradual suppression of the horse as the main user of our roads and streets. That statement brings us back once more to the text we have so often laboured to drive home into the minds of those who control the motorcar industry. What is their object, or haven't they one? At present they seem to be in the clouds, striving after nothing definite. Do they wish to compete against trunk lines of railway? It would seem that the object in France is something of the kind, otherwise why try to run from one end of the country to another at breakneck speed? None but a pack of fools think that the general public can be served by motor carriages carrying a dozen passengers

Digitized by Google

or so from Paris to Bordeaux. Neither passengers nor mercantile needs will be served by anything of this kind. The Liverpool association has shown a much better appreciation of the needs of the times, and has paid particular attention to the mechanical propulsion of heavy weights. There cannot arise the same difficulties with motor work in regards to the local authorities as arises with tramway companies. The latter use the public roads for private gain, and were they to construct their tramways upon their own ground, as railway companies have to construct their lines, there would be no clashing between them and the local authorities. But this is an aside. The Automobile Club and the owners of motorcars are fast enlightening the members of councils to the value of such means of locomotion; and it was a happy thought of the president-elect of the Association of Municipal Engineers to invite an exhibition of automobilism at Leicester the last week of this month, in order to further bring home to municipal engineers the merits of the vehicle of the immediate future.

WANTED, A NAME.

Max Müller and other philologists have written learnedly upon the degradation of words. Up to a quite recent period the term "electrician" was applied to highly-trained scientific men; nowadays it is applied as frequently to an unskilled labourer employed in digging a trench as it is to the scientific student. The weekly annals of our police courts continually record street and other brawls in which an "electrician" figures. The bricklayer's labourer is not a bricklayer, nor the navvy an engineer; and the profession would be benefited sentimentally, if not actually, by the substitution of another name than electrician for the man who is no more an electrician than the man before the mast is an officer.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

PERPETUAL MOTION.

SIR,—I note Mr. Arthur E. Gilbert's letter in your issue of June 7, and am surprised to find that he is still hammering away at "perpetual motion." He accuses you of stubbornness in disbelieving what he says, but the accusation is more appropriate to himself, and I suggest that he is just as likely to be mistaken now as he was when he sent you drawings of his inventions, about 15 months back.

Mr. Gilbert writes: "I have overcome the laws of gravity (you say nature), by utilising the whole weight of the wheel to drive itself by a scientific arrangement of levers and driving weights." Mr. Gilbert has not yet shown that the laws of gravity are not natural laws. The whole weight of the wheel cannot be utilised at once to drive itself. If the shaft is horizontal, what about the ascending half of the wheel? If Mr. Gilbert's apparatus will work at all, it will do so equally well on either a horizontal or vertical axis. In the latter case, it should be evident even to Mr. Gilbert that no arrangement of levers and weights, whether scientific or otherwise, can impart to itself motion in a horizontal plane.

The fact that Mr. Gilbert has not succeeded in producing an arrangement which works is significant. Let him provide sketches and a short description of his design that we may have another opportunity of criticising, and, I hope, of convincing him of the folly of persisting further. May the matter be thrashed out for good this time. I should feel inclined to look for stagnation rather in Mr. Gilbert's apparatus than about the editor of the *Electrical Engineer*. Nothing would give me greater pleasure than to see the arrangement, the uselessness of which I do not think there would be any difficulty in demonstrating.—Yours, etc.,

G. EVANS.

Aberdare, June 8, 1901.

BRIGHTON CABLES.

SIR,—Mr. Gibbings, of the Liverpool Silver and Copper Company, suggests, in his letter to you, that I am wrong in assuming the conductor resistance of the Cable Makers' Association cables should be measured at a temperature of 60deg. F., and endeavours to show that there is practically no difference between the conductor resistance of the cable offered by the Cable Makers' Association and that of the Union Cable Company, Limited, and that, therefore, the cables of all the tenderers are of the same value, because the resistance of the Cable Makers' Association "was most probably based on a standard temperature of 75deg. F."

It is possible he is right, but what better claim has he to his assumption of 75deg. than I to mine of 60deg.? I think if he will look up any cablemaker's catalogue, he will find he is "most probably" wrong. Perhaps the Cable Makers' Association will in its own good time enlighten us as to the temperature.

The latter part of Mr. Gibbings's letter is beside the question.—Yours, etc.,

J. A. BLACKWOOD,
Secretary, Union Cable Company, Limited.

FORTHCOMING EVENTS.

FRIDAY, JUNE 14.

Institution of Electrical Engineers.—At 9 p.m., annual conversazione at the Natural History Museum, Cromwell-road, S.W.

Physical Society.—At 5 p.m., ordinary meeting. Papers: "On Herr Jahn's Measurements of the E.M.F. of Concentration Cells," by Dr. R. A. Lehfeldt; "Exhibition of a Set of Specimens of Jena Glass," by Prof. S. P. Thompson, F.R.S.

WEDNESDAY, JUNE 19.

Meteorological Society.—At 4.30 p.m., ordinary meeting. Papers: "The Eclipse Cyclone, the Diurnal Cyclones, and the Cyclones and Anticyclones of Temperate Latitudes," by Mr. H. Helm Clayton; "The Seismograph as a Sensitive Barometer," by Mr. F. Napier Denison.

Municipal Electrical Association.—Sixth annual convention at Glasgow opens. Among the papers which will be read on this and the following three days for which the meeting is called are: "Uninsulated Returns in a Tramway System," by Mr. J. H. Rider; "Street Electric Lighting," by Mr. W. Maclay; "Braking Apparatus for Electric Cars," by Mr. A. L. C. Fell; "The Equitable Allocation of Costs in Combined Lighting and Traction Stations," by Mr. W. H. Tittensor; "Refuse Destructors in Combination with Electric Power Stations," by Mr. J. S. Highfield; and "Coal and Ash Conveying Gear," by Mr. R. A. Chattock. Saturday, the 22nd, is the last day of the convention.

Institution of Civil Engineers.—Annual conversazione, Great George-street, S.W.

SATURDAY, JUNE 22.

Institution of Electrical Engineers.—Visit to Germany.

IMPERIAL THEATRE.

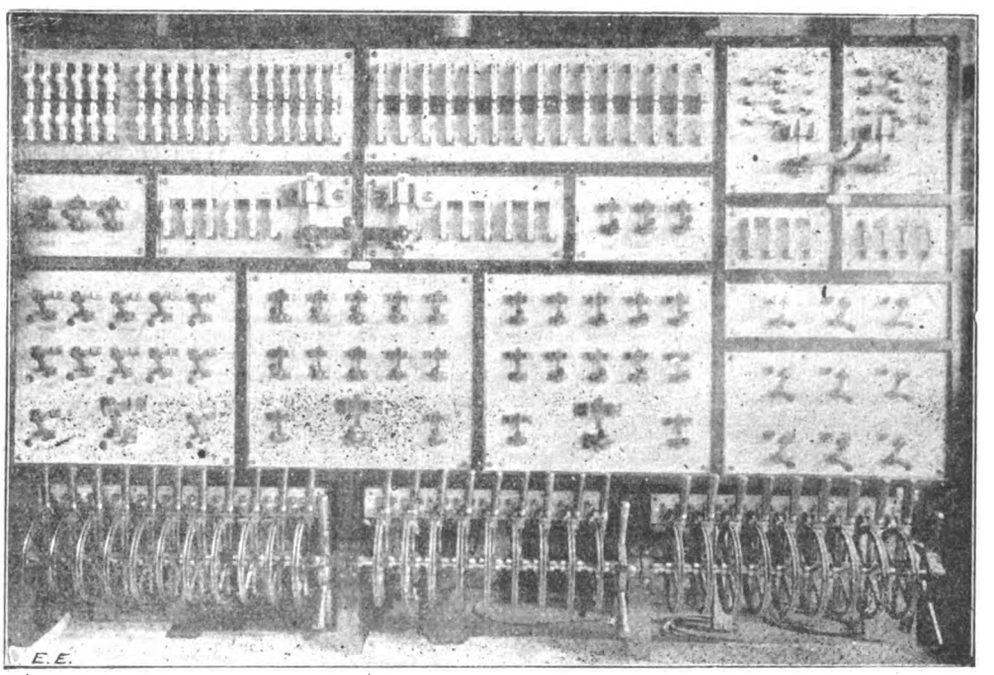
The lighting of this beautiful house marks a new departure in electric lighting. Instead of the usual number of bright points giving out a white and cold light from various candelabra suspended from the ceilings, aided by others fixed on brackets, we have here a remarkably warm effect of diffused light closely resembling the genial sunlight, agreeable to the eye, and most efficient as far as quantity of light is concerned. The main supply of light streams through delicately-tinted amber glass plates from the ceiling, and from battens concealed behind the cornices. A very few metal torches, columns, etc., bearing lamps, uniform in design with the whole idea, are distributed along the walls.

The architectural design of the auditorium, with its coating of light Pavonazza marble, relieved by pilasters and

Digitized by Google

columns of Sienna and darker Chipolini, and its burnished metal ornaments with silk hangings and jewelled embroideries, is thus shown to its best advantage. The stage-lighting is so perfect that an opera glass becomes a superfluity. The scheme includes about 1,650 lamps, varying from 8 c.p. to 32 c.p. each, of which 960 belong to the stage-lighting, and 25 arc limelights of 8, 12, 15, and 20 amperes respectively. There will be three arc lamps of 15 amperes each fixed outside the street entrance. All but two of these arcs are automatic. The stage-lighting has the usual red, white, and blue gamut, a number of hanging battens which can easily be connected to plugs fixed into the flooring of the stage, and various other ingenious contrivances, of which more anon.

As regards the credit due for the electric lighting of the theatre, the idea was Mrs. Langtry's, the designs being executed under her constant personal supervision by Mr. F. T. Verity, F.R.I.B.A., the architect, and Mr. G. C. I. Vaughan, A.M.I.E.E., of Messrs. Vaughan and Brown, Limited, who supplied the fittings and carried out the whole of the work. Going behind the scenes one's attention is drawn to the switchboard, which is faced with 1¾in. white marble. Liquid resistances are used, which are placed in two rooms below the stage. The switchboard is on an elevated gallery in the corner formed by the P. side and the back of the stage, and the operator has an uninterrupted view of the movements on the stage and in the flies. The board is divided by a vertical partition in the two independent sections—the smaller one controlling a 200-volt alternating current, the other a 100-volt alternating current, supplied both from the London Electric Company—one connection being with the Trafalgar-square and the other with the Victoria railway station sub-stations. There are two banked transformers in the basement of the theatre. Another supply is obtained from the Westminster Electric Supply Company. The whole supply can be cut off by means of a capstan switch, occupying the central position amongst the levers at the base of the board. In order to obviate any breakdown which might occur on account of a resistance jar becoming heated after having been in use for a considerable time, a resistance cut-out switch is provided, which allows of any variations being made. In the centre of the upper part of the board there is an 800-ampere throw-over switch for the stage lights. The orchestra and stage lights can be controlled independently of the general supply, so that when the house, and maybe the stage, is in darkness, moonlight and other effects can be worked. The switch fuses are interchangeable, and the whole is so arranged that either they or the brushes of the lever switches can be easily replaced. A separate board controls the arc lights; it is constructed for a 200-volt continuous current supply from the Westminster Company. All the lime arcs can be cut out at once by pulling one lever. There are two automatic arc lamps placed underneath the Royal boxes, which play on the stage, and have the effect to kill the shadows on the faces produced by the light from above. The other arcs are worked from a hanging bridge, which can be moved to any place above the stage by means of centre weights. These arcs have achromatic lenses tested to withstand the heat of a 20-ampere arc, and by an arrangement of switches they can be connected with either the continuous or the alternating current supply. All the fittings in the staircases and passages are of the bulkhead or watertight kind of ship fittings. There are no open fittings and no gas supply whatever. Everything is done by electricity, even the heating of the coffee-urns in the bars. All the battens work on winches, and the work is directed in quite a novel way. A number of lamps are fixed in various parts of the flies, etc., and all scene shifting is controlled silently by means of signals consisting of a number of coloured flashes. These lamps are connected in series with others fixed inside the prompter's desk, so that he can easily meet any excuse as to the light not having shown by confronting the workmen with the counterpart of the signal. Two boards (police circuit), one for alternating and one for continuous current, are placed 6ft. apart in the corridors of each tier. The back of the balcony and the ceilings of the pit and gallery are also lit by bulkhead lights. The ceiling of the main hall consists of an iron framework, into which a number of amber glass plates are let in. Above the same about 400 incandescent lamps are placed. There are battens carrying incandescent lamps behind the cornices. A unique mirror is placed in the dressing-room forming one of Mrs. Langtry's suite of rooms. It is framed by 75 16-c.p. lamps, which can be arranged in any colours so as to match with the corresponding effect of the stage-lighting.



Switchboard at the Imperial Theatre.

THE EDISON STORAGE BATTERY.

The following description of the new type of accumulator invented by Mr. T. A. Edison was given by Dr. A. E. Kennelly at the annual meeting of the American Institute of Electrical Engineers. We are indebted for it to the editor of the *Electrical Review* of New York, who kindly sent us an advance copy of his report of the meeting. Dr. A. E. Kennelly said:

I take pleasure in bringing to the notice of the institute this evening a novel type of storage battery, recently invented by Mr. Edison. It is well known that the history of the storage

Digitized by Google

cell is essentially that of the lead cell discovered by Planté in 1860, in which lead peroxide is the depolarising substance. An enormous amount of labour has in the aggregate been expended upon the improvement of this cell in the hands of experimentalists. As a result of that labour the storage battery has at last become a recognised adjunct to direct-current central stations, but it has limitations that seem to withstand further attempts toward improvement. Of recent years hardly any success has been met with in the direction of reducing its weight for a given energy-storage capacity, without detriment to endurance, and this weight is the great drawback of the storage battery in electric storage traction, and has been the principal obstacle to its advance in this direction for the past 20 years. In practice, the storage energy per unit mass of the modern lead battery is from four to six watt-hours per pound of battery (8·8 to 13·23 watt-hours per kilogramme). Expressed in another way, a battery weighs from 124·5lb. to 186·5lb. per horse-power hour at its terminals (75·5 to 113·4 kilos per kilowatt-hour), or, if its stored energy available at terminals were all expended in gravitational work, a battery could raise its own weight through a vertical distance of from two to three miles (3·2 km. to 4·8 km.). While it is possible to increase the energy per unit mass by making the electrodes very light, yet this is always found to be followed by a very heavy deterioration. Many attempts have also been made to perfect storage cells of the alkaline-zincate type, but the great difficulty of depositing zinc in coherent form from the solution, as well as the lack of a depolariser that shall be insoluble in the electrolyte, has stood in the way of this cell's success.

Mr. Edison set himself the task of finding a cell which should possess the following advantages: (1) absence of deterioration by work; (2) large storage capacity per unit of mass; (3) capability of being rapidly charged and discharged; (4) capability of withstanding careless treatment; (5) inexpensiveness. He believes that the cell here shown may claim these advantages in a very satisfactory degree. The negative pole or positive element, corresponding to the zinc of a primary cell or the spongy lead of a secondary cell, is iron. The positive pole or negative element, corresponding to the carbon of a primary cell or lead peroxide of a secondary cell, is a superoxide of nickel believed to have the formula NiO_2. The cell is therefore a nickel-iron cell, a name which suggests the structural material—nickel-steel. The electrolyte is potash—viz., an aqueous solution containing from 10 to 40 per cent. by weight, but preferably 20 per cent. of potassium hydroxide, the freezing temperature of which is 20deg. below zero Fahrenheit, or 30deg. C. The initial voltage of discharge, after recent charge, is 1·5 volts. The mean voltage of full discharge is approximately 1·1 volts. The normal discharging current rate per unit area of active element (positive or negative) is 60 $\frac{\text{milliamperes}}{\text{square inch}}$, or 8·64 $\frac{\text{amperes}}{\text{square foot}}$, or 0·93 $\frac{\text{amperes}}{\text{square decimetre}}$. The storage capacity of the cell per unit of total mass of the cell is 14 watt-hours per pound, or 30·85 watt-hours per kilo. Expressing the same statement in another way, the weight of battery per unit of electric energy at terminals is 53·3lb. per electrical horse-power hour, or 32·4 kilos per kilowatt-hour. Or the battery gives energy at its terminals sufficient to lift its own weight through a vertical distance of approximately seven miles, or 11·26 km. The mean normal discharging power rate per unit mass of total cell is four watts per pound, or 8·82 watts per kilo, corresponding to a normal discharge period of 3½ hours. The cell may, however, be discharged at a relatively high rate in approximately one hour, corresponding to a discharging power rate per unit of total cell mass of 12 watts per pound, or 26·46 watts per kilo. Charging and discharging rates are alike—that is to say, the cell may be charged at the normal rate in 3½ hours, or it may be charged at a relatively high rate in one hour, with no apparent detriment beyond a somewhat lowered electrical charge efficiency. In other words, the cell does not appear to be injured by over-charging or discharging, and only suffers in electrical efficiency under such treatment. The positive and negative plates are mechanically alike, and can scarcely be distinguished by the eye. They differ only in the chemical contents of their pockets. For automobile batteries each plate is formed of a comparatively thin sheet of steel, 0·024in. (0·61mm.) in thickness, out of which rectangular holes are stamped, so as to leave a grid or frame somewhat resembling a window-frame. Each opening or recess is filled with a pocket or shallow box containing the active material. These boxes correspond to the panes of glass in the window-frame analogy. The panes, instead of being thinner than the frame, as in an actual window, are thicker than the frame, or project slightly beyond the surface of the steel grid. They are perforated with numerous small holes to admit the electrolyte, but entirely conceal the contained active material from view. All that meets the eye, therefore, in any of the plates, is the steel frame, and its embedded "windows" of perforated steel.

The active material is made in the form of rectangular cakes or briquettes, and one such briquette is lodged in each pocket or "window-pane" of the plate. Each briquette is placed in a shallow, closely-fitting nickel-plated box of thin perforated crucible steel, cut from a long strip of that material 0·003in. (0·075mm.) thick. A cover or lid of the same material is then laid over it, so that the briquette is closely enveloped by the sides and walls of its perforated steel box. The boxes are then placed in the openings or holes in the nickel-plated steel grid, and closely fit the same. The assembled plate is then placed in a hydraulic press, and subjected to a total pressure of about 100 tons. This pressure not only tightly closes the boxes, bu it also forces their metal sides over the adjacent sides of recesses in the steel grid, thus clamping the whole mass into a single solid and rigid steel plate with the hollow "window-panes" full of active material. The nickel plating of both grids and boxes aids in securing good permanent electric connections between them. The finished plate has a grid thickness of 0·024in. (0·56mm.), and a "window" or pocket thickness of 0·1in. (2·5mm.). This is the maximum thickness of the plate at any point, but being of steel the plate has ample rigidity. The positive briquettes (zincs of a primary cell) are made by mixing a finely-divided compound of iron obtained by a special chemical process with a nearly equal volume of thin flakes of graphite. The graphite does not enter into any of the chemical actions, but assists the conductivity of the briquettes. The graphite is divided into very thin laminæ by a chemical process, and these are passed through sieves or screens so as to leave a size or area of flake that is much larger than the area of the perforation in the steel windows. The mixture is then pressed into briquettes in a mould under a hydraulic pressure of about two tons per square inch. The briquettes have a surface area of nearly 3in. by ½in. on each face. The negative briquette (carbon of a primary cell) is made by similarly mixing a finely-divided compound of nickel, obtained by special chemical means, with a nearly equal bulk of fine flakes of graphite and solidifying the mixture in a mould into briquettes of the same size as above. A suitable number of positive and negative plates are assembled together, being separated from one another only by a thin sheet of perforated hard rubber.

The assembled plates are placed in a vessel or external containing cell of sheet steel containing the potash solution, which, of course, does not attack steel. There was, however, much difficulty from the action of the potash on the soldered seams of the steel containing vessel. After many trials, however, Mr. Edison found a solder which seems to be entirely unaffected by the alkali. In charging, the current is, of course, sent into the positive pole and its attacked negative nickel plate, through the electrolyte, and into the positive plate of the iron compound which carries the negative pole. This current deoxidises or reduces the compound to spongy metallic iron and carries the oxygen through the film of electrolyte to the nickel compound, oxidising it to the hyper-oxide of nickel, NiO_2, a higher oxide than the peroxide; in other words, the charging current simply carries oxygen in the opposite direction against the forces of chemical affinity from the iron to the nickel, and stores the energy in the reduced iron, which is, of course, unaffected and passive in the presence of the potash solution. On discharge the current passes from the positive pole through the external circuit to the negative pole and its attached iron or positive plate, and then through the solution to the negative or superoxide plate. In so doing the oxygen moves back against the current and partially reduces the nickel superoxide, NiO_2, while oxidising the spongy iron. The energy of burning of the iron and oxygen which would be developed as heat in the ordinary chemical process is now liberated in the circuit as electrical energy.

The cell is an oxygen lift. Charging pulls the oxygen away from the iron and delivers it temporarily to the nickel. The condition is then stable until the circuit of the cell is completed. Discharge then allows the oxygen to fall back from the nickel to the iron with the natural affinity of iron and oxygen. This action is very different from that which takes in the lead storage cell. Here, neglecting complication, the action is usually regarded for practical purposes as being represented by the equation

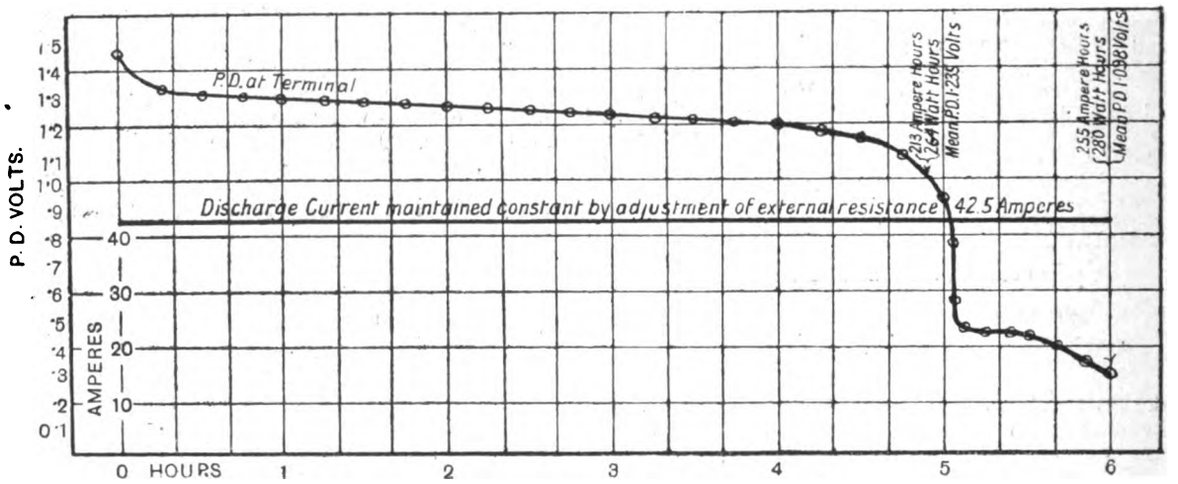
$$PbO_2 + 2H_2SO_4 + Pb = PbSO_4 + 2H_2O + PbSO_4 + 100 \text{ watt-hours},$$

where the left-hand side represents the condition of charge and the right-hand side the condition of discharge. Here oxygen is not simply transferred in discharge from the peroxide to the spongy lead, but the solution is changed (theoretically) from an aqueous solution of sulphuric acid to plain water. Of course the discharge could not practically be carried to the point of denuding the solution of all sulphuric acid, and a surplusage of acid must be used. The equation gives a mere theoretical outline of admittedly very complex reactions. In other words, the specific gravity of the sulphuric acid solution falls during the discharge, and the solution enters into the chemical combination. Theoretically, for every 445 grm. of active material on both plates, 196 grm. of sulphuric acid are required to effect the combination, or 44 per cent. by weight of the active elements,

Digitized by Google

and in practice it is usual to allow a weight of sulphuric acid nearly equal to half the weight of the elements, or about one-quarter of the total weight of the cell.

In the new Edison cell, on the other hand, the theoretical action of the potash solution is merely to provide the proper channel through which the oxygen ions may travel in one direction or the other—positive plate to negative plate in charge, and negative plate to positive plate in discharge. Consequently, the amount of solution needs only to be sufficient to fulfil mechanical requirements. It is believed that the weight of solution will in practice be only about 20 per cent. of the plate weight, or about 14 per cent. of the cell weight. In fact, the cell may be worked in the same manner as the so-called primary "dry cells." Moreover, if the solution should escape, the energy would be entirely that due to the energy of combination of oxygen and iron, stated to be 79·7 watt-hours, and representing an E.M.F., theoretically obtainable, of 1·47 volts. If the combination of oxygen with the nickel compound be exothermic, or energy releasing, then the watt-hours delivered (and the E.M.F.) will be lessened by the energy necessarily paid back to break up the combination. If, on the other hand, the combination is endothermic, or energy absorbing, then the watt-hours delivered (and the E.M.F.) will be increased by the energy restored on breaking up the combination. Since the superoxide seems not to have been known hitherto, no information concerning its energy of combination is obtainable. The E.M.F. of the cell seems to be so near to that of the union of iron and oxygen as to suggest that the nickel superoxide is



Curves of Discharge of Small Multiple Edison Cell Weighing 2lb.

or be carried away by gasing in charging, the only detriment seems to be the loss of active surface thereby occasioned, and it will only be necessary to fill up the cells to the proper level with water from time to time as evaporation or gassing may lower the level. For the same reason the specific gravity of the electrolyte does not appreciably vary during charge and discharge. The briquettes of active material slightly expand on receiving oxygen, and slightly contract on delivering it—that is to say, the iron briquettes contract and the nickel briquettes expand during charge, while on discharge the iron briquettes expand and the nickel briquettes contract. The level of the solution is in this way scarcely affected. The expansions and contractions of the briquettes appear to be well within the elastic limits of the spring-steel containing boxes, and consequently the electric contact is always not far from being neutral, or that the nickel compound has but little affinity for oxygen, although the superoxide appears to be quite stable in the cell.

The new cell does not seem to be appreciably influenced by changes of temperature, and should stand a very low temperature without detriment. The electrolyte—potash—does not attack any of the ingredients of the cell, nor are any of the ingredients soluble therein. No local action occurs in the cell so far as has yet been observed, since the E.M.F. is below that necessary to decompose water. The cell may be fully discharged to the practical zero point of E.M.F. without detriment. In fact, a cell has not only been completely discharged, but recharged in the reverse or wrong direction, and after bringing it back to its originally charged state by proper restoration of the direction of charging current, the storage capacity remained

secure. The covers or sides of the window pockets merely approach to or recede from each other slightly during charge and discharge. Fortunately, steel is a metal which possesses this mechanical elasticity in a marked degree. The action of the charging and discharging current upon the briquettes seems to be transferred from their external surfaces inwards in a manner similar to the transfer of carbon and oxygen in the process of making malleable cast iron in the furnace on the principle of cementation. No active material has been found to be ejected from the briquettes through the window perforations, even under deliberate overcharging and discharging. Such gas as is thereby produced makes its appearance on the external surface of the windows. If the nickel compound had no affinity for oxygen, so that energy was neither developed nor absorbed in the deoxidation or further oxidation of that substance, then unaffected. It would seem, therefore, that the cell should be capable of withstanding much abuse. Diagrams are appended giving the curves of discharge of experimental cells.

Mr. Edison states that "the negative plate (nickel) either charged or discharged can be removed from a working cell and dried in the air for a week without appreciably injuring it, and when the plate is finally replaced in the cell its charge is practically undiminished." The positive (iron) plate, if similarly removed from the cell, will be likewise uninjured, but it soon loses its charge by the oxidation of the spongy iron with accompanying liberation of heat and appreciable rise of temperature extending over a period of several hours. On replacing the electrode, however, in the cell the storage capacity is unaffected on recharge. As regards cost, Mr. Edison believes that after factory facilities now in course of preparation have

Digitized by Google

been completed, he will be able to furnish the cells at a price per kilowatt-hour not greater than the prevailing price of lead cells.

Having now considered the action and properties of the cell, a brief description may be given of the difficulties encountered in developing it. The phenomenon of passivity has probably kept inventors from finding this cell in the past. Mr. Edison believes that of all the very numerous compounds of iron, and of which he has tried many hundreds, the particular compound which he prepares is perhaps the only one capable of being used. If the dried hydrates or oxides of iron, native or artificial, are subjected to electrolytic reducing action in any alkaline solution, they may remain inert and unaffected. On the other hand, if finely-divided iron obtained by reducing a compound of iron under the action of a reducing agent, such as hydrogen or carbonic monoxide, is subjected to electrolytic oxidation in an alkaline solution, it is inert, and cannot be oxidised. It assumes the well-known passive state. The same difficulty of passivity affects the use of nickel or the negative element. Finely-divided nickel, reduced from a nickel compound, remains inactive when subjected to electrolytic oxygen in an alkaline solution. The monoxide and the black oxide or peroxide are also inert. No oxide of nickel is active or can be made active by electrolytic action, and the peroxide does not act as a depolariser.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

385. In a house-lighting installation with three-quarter mile distance between the power-house and the house, would it be feasible to regulate the voltage on the lamps automatically by means of an adjustable resistance placed at the house and regulated by an electromagnetic device, and if so, what would be the best and most reliable arrangement? Has a similar arrangement been used at any existing installation which you know of, and with what success? The voltage at the power-house is assumed to be kept constant, but the lamp load is assumed to vary from 5 to, say, 100 16-c.p. lamps.—R. M. W.

386. Describe and illustrate the method of distribution adopted in three-phase currents, the high-tension current being transformed down to 220 volts. Arc and incandescent lamps are to be used, and, if possible, on the same circuits or phases. Explain the method of dividing the load amongst the three phases.—R.

ANSWERS.

Question No. 379.—What is considered the best form of gearing on electrically-driven pumps for silent running and durability? Has chain gear met with any success?

Best Answer to No. 379 (*awarded* 10*s.*).—Pumps are of many kinds, and gearing which is quiet and durable enough for one pump is quite unsuitable for others. For instance, a centrifugal pump runs with a steady load which does not vary during a revolution of the fan. A single-acting, single-plunger pump, on the contrary, has a load varying from zero to a maximum and back to zero on the inward stroke, and may even have a negative load on the outward stroke. Double and treble plunger and double-acting pumps have a more constant load at various phases of the revolution, but it is this variation of load causing change of stress on the gearing which is the cause of noise and wear. Driving by means of ropes, with V-grooved pulleys, or by belts is the best method to adopt where possible, but as electric motors run at a fairly high speed, say 500 to 1,000 revolutions per minute, and reciprocating pumps run at a speed of 40 to 70 revolutions per minute, a single reduction (using belts or ropes) is not possible, as the arc (of the small pulley) embraced by the belt is insufficient to prevent slipping with a reasonable belt tension. Owing to the amount of floor space required, a double reduction by means of belts or ropes is seldom advisable. Ordinary spur gear is noisy, and spur gear with cut teeth soon becomes nearly as bad owing to the teeth of the spur wheel wearing unequally, due to the turn of the stroke of each crank. Double helical spur gear is satisfactory as to durability, and is a great advance upon ordinary spur gear as regards quiet running. For moderate sized pumps, up to say 30 b.h.p., rawhide pinions gearing into cut cast-iron or steel spur wheels leave little to be desired. The pinions are most quiet when the gunmetal flanges, which hold the rawhide blanks together, are not carried up to the points of the teeth, but stop short at the roots. If carried up, the gunmetal teeth wear unequally with the hide, and cause noise and grinding. These pinions must be run dry, or blacklead lubricant only used, as oil or tallow softens the hide. The writer had occasion to try a rawhide pinion for driving some machinery by electric motor some time ago. The motor and gear were carried at the top of the main walls of a large office building, and cast-iron spur gear with cast teeth was at first used. Complaints of vibration were so frequent that the writer was called in to effect a remedy, and by substituting a rawhide pinion, while retaining the cast spur wheel, the noise was greatly reduced. The gear has been in almost constant use for 18 months with very little wear. In ordinary cases, rawhide pinions and cut cast-iron spur wheels are most suitable. Where expense is a secondary consideration and freedom from noise and vibration most essential, the best results are obtained with worm gear having a steel worm carefully cut from the solid gearing into a gunmetal wormwheel, which is also accurately cut from the solid, so mounted in a closed oil bath that the worm gears with the wheel below the surface of the oil. The motor should be coupled to the worm by a rigid, not a flexible, coupling, and the only noise will be the knock in the connecting rods of the pump and in the valves. The worm gear will be noiseless. The durability of this worm gear, when well constructed, is astonishing. The writer has had under his observation for the last seven years a worm gear (as described above) driving a three-throw pump, which starts and stops automatically, keeping a hydraulic accumulator charged. It has worked continuously night and day for the period mentioned, actually running probably one-half of the time, and the worm gear, though worn, will probably last two or three years longer, and the noise is trifling—in fact, the motor makes more noise than the gear. For centrifugal pumps any gear will be fairly quiet and durable, but a motor direct-coupled to the pump is the ideal arrangement. Chain gear has been used, chiefly for very small pumps, but it has not been successful, owing to the jerk on the chain as the cranks turn the centre. Sparking at brushes is apt to be caused by this.

Answer to No. 379 (*awarded* 5*s.*).—No type of pump is specified in this question, and as there are two forms commonly used in a modern electric generating station, both will be considered here. The two types of pumps are the centrifugal and the two or three throw plunger pump. With the first named, it is undoubtedly best to dispense with all gearing by coupling the armature spindle of the motor direct to the spindle of the centrifugal pump. If for any cause this cannot be done, then the power should be transmitted by belting. In the case of large centrifugal pumps two belts are often used, one being at either end of the pump spindle. For the two and three throw plunger pumps a different arrangement has to be adopted. These pumps are run at too slow a speed to be able to couple the motor direct to the crank axle. They are usually sent out by the manufacturers with a spur wheel attached to the end of the crankshaft, this gearing into a pinion on a countershaft, at the other end of which a place is provided for a belt pulley or spur wheel. The most compact way of driving is to gear direct from the motor into a spur wheel on this countershaft. It is, however, sometimes done by belting, which has the advantage of comparative silence in running, but is not so efficient as gearing, and is always

Digitized by Google

liable to give trouble. This method is, in fact, being rapidly superseded by gearing. For gearing, the best method is to make all pinions of rawhide, and to use cast-iron spur wheels with machine-cut teeth. This should give fairly silent running, though not as silent as belt driving. The rawhide pinions will probably not be as durable as the belt, but, on the other hand, will be very much cheaper to replace.

Another form of gear (chiefly used for pumps of large size) is that in which the spur wheel is made with a cast-iron frame, with hardwood teeth tenoned in. The pinion in this case is of cast iron, and should have machine-cut teeth. This form is slightly more silent than that with the rawhide pinion. The wood-toothed spur wheels are, however, very expensive to replace. It is also not quite so efficient as the rawhide pinion.

Still another form of gear is the worm and wormwheel. This gives very silent running, and all intermediate gearing may be dispensed with; but, nevertheless, it is not as efficient as the spur and pinion, nor as durable. It also has the disadvantage that the pump cannot be moved either way for the purpose of making any adjustment except by running the motor, or by putting the worm out of gear. Cast-iron, in place of the rawhide pinions mentioned above, may, of course, be used. They will be slightly more efficient, but noisier.

For silent running, the different methods of gearing may be placed as follows: (1) worm and wormwheel; (2) belting; (3) wood-toothed spur wheel and cast-iron pinion; (4) cast-iron spur wheel and rawhide pinion; (5) cast-iron spur wheel and pinion. There is very little, indeed, to choose between (3) and (4), and belting (2) will not be very much more silent than these.

For durability, they may be placed in the following order: (1) cast-iron spur wheel and pinion; (2) belting; (3) cast-iron spur wheel and rawhide pinion; (4) wood-toothed spur wheel and cast-iron pinion; (5) worm and wormwheel.

Chain gearing has not been found successful. There is much trouble caused by stretching and breaking of links. It is also by no means silent running. A further objection is that the chain must be kept well lubricated, and throws the oil or grease to a considerable extent.—E.M.R.

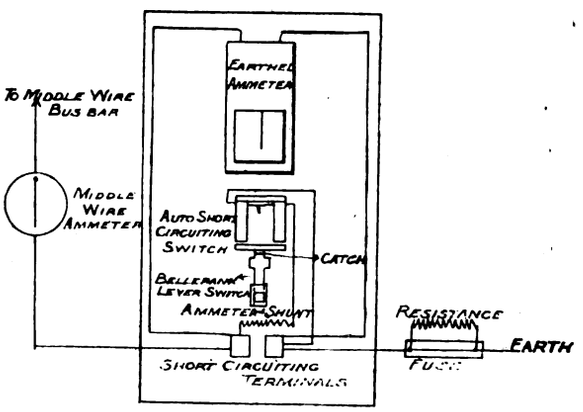
Answer to No. 379 *(awarded* 5*s.).*—It would be hard to say which is the best form of gearing for pumps. The form most favoured by makers (for positive driving) is spur gearing; it runs well, is efficient, and, if the pitch speed is not high, fairly silent, and could be made more so by using a rawhide pinion and cut teeth or hardwood teeth in one of the wheels. It is better to put the wood teeth in the larger wheel, as the life of a tooth will be longer under these conditions, not coming into gear so often. A good ratio for spur gearing is 4 : 1. In practice, a double reduction is usually used, thus adding to the noise and reducing the efficiency. Yes; chain gearing is used for electric pumps, and if well designed, chain speed low, etc., would be very suitable. Those the writer has seen were old, with a high chain speed, and some of the rollers missing. They were naturally noisy. A good form of chain for low speeds is made by Hans Renolds, called the "flat-back chain," and although the writer has not seen it employed for pump work he thinks it would be suitable. Fig. 1 gives

Fig. 1.

the form of a few links. For higher speed the bicycle form of chain might be used with this form. Speeds from 1,000ft. and 1,500ft. per minute may be used. The great objection to chain gearing is the altering of the pitch, no matter how good the chain. It is a question of time, and when the pitch alters chains begin to be noisy and dangerous, and they are liable to mount the teeth and so snap. Although modern practice seems to have forgotten belting for this sort of work, it can be found in some of the Scotch mines running well at this moment, one of the great objections to it being the space necessary for the drive. Worm gearing is also much used for pump work, and is very suitable. The reduction may be 8 : 1. Thus a single reduction only is necessary, thus bringing its efficiency up to the spur gearing. It is also silent and takes up small space. Touching the durability, allowing all forms to have the best material, workmanship, and running under the same conditions, spur gear would have the longest life, worm gearing makes a good second, chain a bad third, unless it has a very low speed; this not being suitable for electric motors, it may be counted out of the running. In worm gearing, one phosphor-bronze and one steel wheel is usually employed, the reason being the low coefficient of friction between these two metals.—T. W. S. H.

Question No. 380.—Give a sketch and discuss the merits and demerits of an earthing panel for the middle wire of a three-wire continuous system of distribution.

Best Answer to No. 380 *(awarded* 10*s.).*—An earthing panel consists of a recording ammeter reading from 0 to 5 or 10 either way, usually of the Elliott type, and an automatic short-circuiting switch, which short-circuits the ammeter if the current to or from earth rises beyond the range of the instrument. A fuse is often placed in circuit with the earth connection, but this is, I believe, against Board of Trade rules. A good way is to place a substantial resistance across the fuse, so that in event



of a dead earth on the mains the fuse would blow, leaving the resistance in, thus preventing damage to plant. If the supply is at 450 volts across the outers, about 10 ohms would allow 22 amperes to flow to earth, which, I think, will satisfy the Board of Trade for a small station. The advantages and disadvantages of earthing the middle wire were dealt with at some length in this paper a month or so ago, and need hardly be dealt with again; and it need only be said that as the Board of Trade require the middle wire to be earthed, it is desirable to know a little of what is taking place with regard to earth leakage. Unfortunately, the ammeter does not tell us much, for if the leakage from both outers is equal the ammeter will register zero. In practice, however, the negative main always falls below the positive, as the negative attracts moisture and the positive repels it. The negative main always has a downward course, but the positive generally keeps up to the mark pretty well. As the ammeter is over to the negative, if an earth occurs on the positive it will fetch it back again, and some idea can be got of the insulation. If an earth occurs on the middle wire, the earthed ammeter will follow to a certain extent the middle-wire ammeter, for the out-of-balance current will flow through the earthed ammeter to earth, through earth to the leakage, and on to the middle wire.

CATALOGUES RECEIVED.

From the General Electric Company we have received their new instrument list, in which we find everything—ammeters, voltmeters, electricity meters, automatic cut-outs, etc.—most clearly described. Our special attention, however, is drawn to the firm's "Stanley" instruments, the "Stanley-d'Arsonval," and the portable and automobile instruments, and the Aron meter, which is so well known that it calls for no comment on our part. In this list the firm devote a special space to automatic cut-outs, and also to an automatic time switch described further on in the list.

LEGAL INTELLIGENCE.

VIBRATION NUISANCE.

An interesting action, Kite *v.* New Grand (Clapham Junction), Limited, came before Mr. Justice Joyce in the Chancery Division of the High Court this week, the plaintiff seeking an injunction to restrain the defendants from causing an alleged nuisance by so using their engines which generated the electric light for the theatre as to produce vibration in the plaintiff's house.

The plaintiff stated that although there was a row of houses between his domicile in Severus-road and the theatre, the engine caused his windows and furniture to rattle, and prevented him and his family securing refreshing sleep. Unless a person had the hide of a rhinoceros, he alleged, he must feel the annoyance.

Another witness, described as a musician, complained that the noise so irritated his wife that she worried his life out, while the beating of time by the engine did not quite synchronise with the time to which the music he was practising was set. He had to plug up his windows and take down his pictures.

Another lodger, who in his leisure hours does a little amateur photography, alleged that the vibration caused the bottles in his dark-room to rattle and annoy him. It also shook his lamp-shade, his windows, his chair, and his venetian blinds.

A fourth witness said there was "no earth tremor, but the atmospheric concussion from the exhaust steam rattled the windows" both at the front and back of his house, especially when the wind was blowing his way.

Witnesses for the defendants stated that they never noticed any vibration.

His Lordship said this was not a case in which, when the matter had been brought to the attention of the defendants, they had immediately taken steps to remedy it, and it was only last Friday that they had taken any effectual precautions. An injunction must be granted, and he would give the plaintiff £5 damages and award him his costs.

Judgment accordingly.

AN ELECTRIC BATH.

In the King's Bench Division an action brought by Mr. and Mrs. John Gwynne against the Medical Electro-Thermic Generator Company, Limited, and another, to recover damages for personal injuries caused, as alleged, by the negligence of defendants' servants while administering an electric bath to Mrs. Gwynne, resulted in a verdict for the plaintiffs, with ½d. damages.

ELECTRICITY SUPPLY AT KEIGHLEY.

An application was made at the Bradford County Court on behalf of the Fleece Mills Company Limited, of Keighley, last week for permission to alter their articles of association.

Mr. Richard Watson, who appeared for the company, said that they were the owners of mills and other premises in the centre of Keighley, and they had the power to supply gas both as an illuminant and as a motive power. They now wished to have their articles of association so altered as to enable them to supply electricity for the same purposes.

Mr. T. R. D. Wright opposed the application on behalf of the Keighley Corporation, contending that by a strict interpretation of the articles of association the company were entitled to supply gas to their tenants only.

In giving judgment, the learned **County Court Judge** pointed out that there was nothing to prevent the attainment of the object desired by the company if they wound up the present company, and formed a new one; and he could not understand how the interests of the Corporation could be affected by allowing the company to do the same thing by the simple and easy process of altering their memorandum of association. As for supplying electricity to persons other than their own tenants, they would have to get special powers to pass under streets; but there was no reason why they should be prevented from applying for such powers. He therefore confirmed the alterations in the memorandum of association. Judgment accordingly.

SMOKE NUISANCE AT HALIFAX.

The Halifax Corporation were summoned before the borough magistrates this week at the instance of the Health Committee for an alleged smoke nuisance at the electricity works.

Mr. Terdoff, for the prosecution, said the Health Committee were charged with the duty of seeing that these smoke nuisances were abated, and they felt that they could not take proceedings against other persons whilst a similar nuisance was created by another department of the Corporation. In consequence of complaints having been made by other people than those in the Corporation, observations were taken by the inspectors. On Dec. 7 the chimney was watched from 1.50 to 2.30 during which time black smoke issued for 10 minutes. On Dec. 10, from 2.45 to 3.45, black smoke issued for 19 minutes. On the matter being reported to the Health Committee, they ordered the usual notice to be served, calling attention to the nuisance, and requesting that it should be abated. After the time specified in the notice had expired further observations were taken, and for some little time there was an improvement. On April 8, from 2.10 to 3.10, black smoke issued for eight minutes. On May 14, from 2.20 to 3.20, the duration was 13 minutes, and from 3.29 to 4.29 five minutes. The limit allowed by the committee was five minutes.

The defendants were not represented, but a letter from Mr. Street, the manager, stated that they had several times tried various so called smoke preventing appliances, but without good results. About two months ago £320 was spent on one, but it was not satisfactory. They were doing their utmost to meet the difficulty, and other methods were being adopted, but they were handicapped by the constantly varying load.

The **Chairman** said the Bench considered this a very gross case. It was one of the worst brought before them for a long time. The Health Committee had done a very proper thing in taking these proceedings. If they had not proceeded against the Corporation, it would not be much good proceeding against anyone else. The excuse in this matter was just the same as was generally given by other firms. The smoke nuisance was very great, and ought to be put down more severely. There was no more excuse why the Corporation should not put their chimneys right than why other people should not put theirs right. The Corporation would be fined £5 and costs, and an order made for abatement.

CLAIM FOR ELECTRICAL WORK.

In the Westminster County Court on Friday, before his Honour Judge Lumley Smith, the case of Wells *v* Chator was tried. It was was an action by the plaintiffs, a firm of electrical engineers carrying on business at 56, Paddington-street, W., to recover the sum of £21. 13s. in respect of electrical work carried out to his order.

Mr. A. B. Raynes, a member of the plaintiff firm, said that in the ordinary course of business the defendant asked for an estimate for certain electrical work which he desired to have carried out. An estimate was supplied and approved, and in due course the work was completed, but the defendant had disregarded all applications for payment, and consequently this action was brought.

Mr. Frank Hills, second engineer to the borough of Hammersmith, said he had inspected the plaintiff's work in order to see that it was done to the satisfaction of the Council. He found that it was well done in every way, and that the charges were reasonable.

His Honour gave judgment for the plaintiff firm for the amount claimed, with costs.

TELEPHONES.

In the Debts Recovery Court, Scotland, last week the National Telephone Company, Limited brought an action against a local solicitor for payment of £3. 18s. 2d. for trunk dues and £8. 15s. of rent payable at March 29 last for use of telephones for the ensuing year. The defender admitted the claim for trunk dues, but objected to pay the rent on the ground that the company had on April 15 cut off his connection with the exchange, and that it was not competent for them to sue for the forehand rent of a subject of which they had deprived him the use. He would have had no objection to pay if the use of the telephone had been continued to him.

The **Sheriff-Substitute**, however, was of opinion that if a customer of the company did not pay his forehand rent the company could both sue him for it and disconnect him from the exchange till he paid. He therefore granted the decree asked for with costs.

Another action brought by the National Telephone Company against Mr. E. G. Fletcher to recover £8, one year's subscription in advance for connection with the telephone system, was disposed of in the Southend County Court.

His Honour eventually gave judgment in favour of the plaintiffs on the ground that although the defendant doubtless intended to terminate the agreement of £8, he had, in fact, not done so.

COMPANIES' MEETINGS AND REPORTS.

NORWICH ELECTRICITY.

The directors in their report for the year ended Dec. 31, 1900, state that, notwithstanding a great advance in the price of coal, and the fact that a considerable sum which has been spent in renewals has been charged to revenue, the directors are able to maintain the same rate of dividend as that declared for 1899, without having had occasion to advance the rates charged for current. During the year many new customers have been acquired, and the number of lamps wired and motors worked from the Company's mains is now much larger than at any former time. The constantly increasing demand for current and the extension of mains during the last two years have involved a considerable expenditure on capital account, for which the directors have obtained a temporary loan from Barclay and Co., Limited. In order to discharge this, and to provide the further capital which will be necessary for the development of the Company's business in 1901, the directors propose to offer to the shareholders, *pro rata*, in the proportion of one new to every four old shares held by them, 1,750 of the 3,000 £16 shares still unissued, at a premium of £4 per share. Including £125. 9s. 10d. brought forward from last year, and allowing for interest on debentures, bank interest, and depreciation, the revenue account shows a credit balance of £4,457. 4s., out of which the directors

Digitized by Google

propose to pay a dividend of 6 per cent. (free of income tax), absorbing £4,200, and to carry forward the balance of £257. 4s.

TELEGRAPH MANUFACTURING.

The ordinary general meeting of the shareholders in this Company was held on the 7th inst. at Liverpool, Mr. James Taylor (chairman) presiding.

The Chairman, in moving the adoption of the report, said that last year they made a profit of £41,284, whereas this year it was £35,183. The difference had been caused by two reasons. In the first place, last year they had an exceedingly good contract, which did not extend to the year now closed. In the second place, last year was one of great difficulty in making their goods, for during that time they practically reorganised the whole factory. Where they used to drive with steam-engines, they now used electric power, and the machinery had had to be altered to have that power applied. They therefore thought it better to put forward their best endeavours to get the works into thorough working order before beginning to tender. They were now in a position to do so, and they had every right to expect a share in some of the large contracts which were being given out by various corporations. Out of the profits they had paid a preference dividend, also the small expenses of issuing the new shares. They had paid an interim dividend on the ordinary shares at the rate of 8 per cent. per annum, and out of the balance they transferred £6,500 to the reserve fund, £4,442 to depreciation account, and they proposed to pay a further dividend of 6s. per share, with a bonus of 2s., making in all for the year a dividend at the rate of 12 per cent., the same as last year. Turning to the balance-sheet, their property with machinery and buildings had been increased by some £16,374. The stock-in-trade was very much larger this year, but it was all good stock, and a large portion of it was some raw material which they bought for a special order in hand. On the other side of the balance-sheet the reserve account now stood at £55 000. In the report it was stated that the telephone industry would become a most important branch of the Company's business, and in view of that and the fact that the Liverpool factory was being worked to its utmost capacity, they were taking the necessary steps to meet the increased demand. A great many towns had gone into the question of providing their own telephone exchanges, and for some years the Company had made a speciality of equipments for the big central switchboards used by telephone companies. He believed they were the only firm in England who had made these to any extent. Previously they all used to come from America. They had fitted up a very large number of exchanges for the National Telephone Company, and when two towns, Glasgow and Tunbridge Wells, gave out their orders for central boards, he was glad to say that they secured both. In addition to that, only last night he had heard that another important town had given a contract to the Company, so that they were in the unique position of having secured the only orders for these boards which had been given. They were fearfully pushed for space, and they had, therefore, in Liverpool practically negotiated for the necessary land upon which to put a proper factory. He moved the adoption of the report.

Mr. J. S. Harwood Banner seconded the motion, which was ultimately adopted unanimously, a vote of thanks to the chairman concluding the proceedings.

NEW COMPANIES.

The following new companies have been registered since our last issue:

J. Stenner and Co., Limited.—Capital, £15,000 in £5 shares. Object: to acquire the business of Messrs. J. Stenner and Co., and to carry on the business of manufacturing and electrical engineers, etc.

Priory Motor, Limited.—Capital, £5,000. Object: to adopt agreements (1) with Arthur Hallet and Co., Limited; (2) with C. L. Loveridge; (3) with the Crawford Gear Company, Limited; and (4) with the Hamilton Motor Patents Syndicate, to carry on the business of engineers, makers and repairers of motors, motor-carriages, etc.

Magnus Volk, Limited.—Capital, £10,000, in £1 shares. Object: to acquire, undertake, and work the electrical tramways on the beach in the borough of Brighton, east of the west entrance of the Aquarium, now worked by Magnus Volk, under the sanction of the Brighton Town Council, and any additions to and extensions of the said tramway; to carry on the business of tramway proprietors, electrical and general engineers, etc.

Ham, Baker, and Co., Limited.—Capital, £40,000, in £1 shares. Object: to acquire the business of Messrs. Ham, Baker, and Co., 13, Grosvenor-road, Westminster, and the Municipal Engineering Works, Langley, Worcestershire, and to carry on the business of ironfounders, mechanical, sanitary, water supply, and electrical engineers, manufacturers of electric and steam motors and machinery, contractors for public works, promoters, etc.

APPOINTMENTS VACANT.

Tramways Manager, South Lancashire Tramways Company. Details in our advertisement columns.

Charge Engineer, city of Bristol electricity department, £3 per week. Details in our advertisement columns.

Instructor in Electric Wiring Classes, two evenings per week, Battersea Polytechnic, £35 per session. Details in our advertisement columns.

Meter Inspectors, borough of Nelson, 30s. per week, June 15; Bradford, accustomed to Ferranti, Thomson, and Bastian meters preferred, 30s. per 50-hour week. Details in our advertisement columns.

Student Demonstrator in Mechanical and Electrical Engineering, for session September to July, part time only, Battersea Polytechnic, £50. Details in our advertisement columns.

Resident Engineers, Grays Urban District Council and Epsom Urban District Council, not exceeding £3 per week.

Electrician, for meter testing department. Details in our advertisement columns.

Private Assistant to manage small electrical installation. Details in our advertisement columns.

Partner to invest in well-established electrical engineering business. Details in our advertisement columns.

Salesman-Traveller with good electrical connection. Details in our advertisement columns.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Brighton.—The Guardians require tenders for the wiring of the workhouse.

Taunton.—The Corporation invite tenders for free wiring. Tenders by July 1.

Stepney.—The Borough Council invite tenders for supply of arc lamp carbons for the year ending June 30, 1902. Tenders by June 26.

Wigan.—The Electric Light and Tramway Committee invite tenders for 12 double-deck single-truck electrical cars. Tenders by June 18. Details in our advertisement columns.

Blackburn.—Tenders are invited for the supply of wrought-iron tubes, and for the supply of steam coal required during the next 12 months. Tenders by June 21. Details in our advertisement columns.

Nelson.—The Electricity and Tramways Committee invite tenders for supply, etc., at their electricity works of a travelling crane. Particulars may be obtained from Mr. W. Alan Fraser. Tenders by 25th inst.

Digitized by Google

Whitehaven.—The Water and Lighting Committee invite tenders for the purchase of about 20 tons of second-hand rubber-covered cables. Tenders by June 24. Particulars in our advertisement columns.

Leigh.—The Tramways and Electricity Committee invite tenders for the supply of electricity meters for a period of 12 months ending June 30, 1902. Tenders by June 22. Details in our advertisement columns.

Barking.—The Urban District Council invite tenders for the supply and delivery of 50 cast-iron street lamp columns. Particulars may be obtained from Mr. C. F. Dawson, surveyor to the Council. Tenders by June 19.

Nelson.—The Electricity and Tramways Committee invite tenders for supply and erection of a generating set. Particulars may be obtained from Mr. W. Alan Fraser, borough electrical engineer. Tenders by 18th inst.

Poplar.—The Electricity Committee invite tenders for the supply of multiple-core lead-covered feeder and network cable and accessories for mains extensions. Tenders by July 2. Particulars in our advertisement columns.

West Ham.—The Council invite tenders for two 500-kw. continuous-current tramway generators, coupled direct to three 850-i.h.p. steam engines, and 11 water-tube boilers. Tenders by June 25. Details in our advertisement columns.

Christiania.—The Government Railways invite tenders for 37,660 ko. 4mm. galvanised iron wire, 9,300 ko. 3mm. galvanised iron wire, 12,800 insulators, etc. Tenders by June 26. Particulars, etc., at the office, Jernbanetorvet 8-9, Christiania.

Madrid.—The Public Works Department of the Department of Agriculture, Madrid, invite tenders for the construction and working for 60 years of an electric tramway from Santiario de la Yedra to Balza. Tenders by July 26. Particulars at that office.

Rotherham.—The Corporation invite tenders for the wiring of the police buildings preparatory to a supply of electricity from the Corporation mains. Specification, etc., may be obtained from the borough electrical engineer, Mr. E. Cross. Tenders by 20th inst.

Leith.—Tenders are invited for one Lancashire boiler, with Galloway tubes (similar to the present installation), and additional steam-piping, at the electricity works. Specifications, etc., may be obtained from the Burgh Electrical Engineer. Tenders by 19th inst.

Amsterdam.—The South Holland Electric Railway Company invite tenders for the supply of 3,600 tons of steel rails with appurtenances. Specifications, price 2fl. (3s. 4½d.), may be obtained from the engineers, Beversen and Van Heurn, The Hague. Tenders by June 15.

Barking Essex).—The Urban District Council invite tenders for the supply and erection of condensing plant, comprising surface condenser, cooling tower, electrically-driven air and circulating pumps, steam grease extractor, pipework. Full particulars, etc., may be obtained from the Engineer, Electricity Works, East-street. Tenders by June 19.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

Epsom.—The Urban District Council invite tenders for supply of meters (direct-current) and cut-outs. Specifications, etc., can be obtained from Mr. E. G. Wilson, clerk, High-street, Epsom, on deposit of £2. 2s. for each specification, returnable on receipt of a bona fide tender. Specifications may be seen at, but not obtained from, the offices of Mr. W. C. C. Hawtayne, 9, Queen-street-place, London, E.C. Tenders by 12 noon on 22nd inst.

London, N.E.—Tenders are invited for the erection and construction of mechanical coaling apparatus for the municipal electricity works, for the Electric Lighting Committee of the metropolitan borough of Hackney. Specification, etc., may be obtained at the offices of Mr. Robert Hammond, M.I.C.E., consulting engineer to the Corporation, 64, Victoria-street, Westminster, London, S.W., on payment of £1. 1s. Tenders by 4 p.m. on July 4.

London, S.E.—The Borough Council invite tenders for the supply of electricity meters, demand indicators, and main fuses. Specifications, etc., can be obtained at the Town Hall, Spa-road, Bermondsey, on payment of a fee of £3. 3s., which will be returned on receipt of a bona fide tender. The specification may also be inspected (but not obtained) at the offices of the engineers, Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by noon on July 1.

Manchester.—Tenders are invited for the supply, delivery, and erection at their Stuart-street generating station of five electrically-driven overhead travelling cranes, for the Electricity Committee. Specifications, etc., may be obtained on application to Mr. F. E. Hughes, secretary, Electricity Department, Town Hall, Manchester, on payment of fee of £2. 2s., and may also be inspected, but not obtained, at the offices of the engineers, Messrs. Kennedy and Jenkins, 17, Victoria-street, Westminster, S.W. Tenders by 20th inst.

Mansfield.—The Corporation invite tenders for the supply and erection of—boiler-house plant: three Lancashire boilers, mechanical stokers, steam pumps, economiser, and motor; engine-house plant: three 200-kw. high-speed steam generators, motor transformer, balancing motor transformer, and accessories; Korting condensers and electric pumps, switchboard and instruments, accumulators, overhead travelling crane, electricity supply mains; public lighting: arc lamps, posts, and accessories; meters, and workshop equipment. Tenders by July 12. Details in our advertisement columns.

Erith.—The Urban District Council invite tenders for the supply and erection of two Lancashire boilers, with fittings, economiser, feed pumps, etc.; pipework, etc., in engine and boiler house; surface-condensing plant, three steam alternators (vertical enclosed high-speed engines direct coupled to three-phase alternators), main switchboard and connections, 10-ton engine-room travelling crane, transformers, sub-stations, and equipment, underground mains, conduits, roadwork for private and public lighting, arc lamps (open type), posts, and station lighting. Tenders by June 24. Details in our advertisement columns.

Cleckheaton.—The Urban District Council invite tenders for the supply and erection of the following plant: (Section C) engines, dynamos. Tenderers must tender for the whole of the section, and not for part of it. Specifications, etc., may be inspected at the offices of Messrs. Gibbings and Baker, Piccadilly-mansions, 17, Shaftesbury-avenue, London, W., and Old Bank-chambers, Cheapside, Bradford, on and after 8th inst., and may be obtained on application to the Clerk of the Council, Town Hall, Cleckheaton, on payment of the sum of £2. 2s., which sum will be refunded on return of specification with bona fide tender. Tenders by 22nd inst.

RESULTS OF TENDERS:

Aston.—The District Council have accepted the tender of Handley and Shanks, at £400, for wiring in connection with the destructor.

Swindon.—The Corporation have sealed a contract with Siemens Bros. and Co. for the supply of two steam dynamos for the generating station.

Rhyl.—The Hart Accumulator Company, Stratford, E., have secured the order for the supply of storage battery required for Rhyl electric lighting.

Colchester.—The Town Council have accepted the amended tender of J. A. Kuner of £45 for adapting the installation at the Military Hospital to take current at the higher pressure.

Battersea.—The Lighting Committee have accepted the offers of Geipel and Lange and the Schattner Electricity Company to supply 12 prepayment meters each at £58. 13s. 5d. and £41. 11s. respectively.

Doncaster.—The Corporation have accepted the tender of Mr. H. Gielgud, 140, Leadenhall-street, London, for steel grooved girder tramway rails for eight miles of tramways in the borough of Doncaster and neighbourhood.

Walsall.—The tender of T. Parker, Limited, Wolverhampton, for supplying and erecting the new transformer required for the Freer-street sub-station, at £780, and for supplying a spare armature for such transformer, at £266, has been accepted.

Fulham.—The following tenders have been accepted: C. Cooper and Co., for the installation of an electrically-driven fan, 18in. in diameter, at £22. 15s.; Boult Bros., for the supply of engine oil for the twelve months ending March 31, 1902, £135. 9s.

Kirkcaldy.—The Town Council have agreed to accept the following tenders in connection with the tramways and electric lighting for the town: Laurence, Scott, and Co., Norwich, engines and dynamos, £6 620; Tudor Accumulator Company, London, storage battery, £1,364, with £80 annual charge for maintenance; Carrick and Ritchie, Edinburgh, overhead travelling crane, £370.

Hornsey.—The District Council have received the following tenders for erection of an electric lighting station in Tottenham-lane, Hornsey:

F. G. Minter, Page-street, Westminster	£16 970
Lole and Lightfoot, Chelsea	16 941
G. Munday and Sons, Trinity-square, E.C.	16,658
C. G. Hill, Coventry	16,500
J. Christie, Richmond-road, W.	16,360
W. Gregar and Son, Stratford	16 183
W. Lawrence and Son, Waltham Abbey	15,999
J. Willmott and Sons, Tottenham-lane, Hornsey	15,990
Wilkinson Bros., Finsbury Park	15 951
F. and E. Davey, Southend-on-Sea	15,495
Braid, Pater, and Co., Bow-churchyard, Cheapside (accepted)	13,777

Hull.—The Electric Lighting Committee have received the following tenders for 12 direct-current street arc lamps, erected complete with cast-iron posts and spare parts and accessories:

Oliver and Co., Burrage-road, Woolwich (accepted	£368	6	6
Verity, Limited, Hardman-street, Manchester	348	14	0
Improved Electric Glow Lamp Company, Limited, 11, Victoria-street London, S.W.	351	0	0
Siemens Bros. and Co., Limited, Woolwich, Kent	352	8	0
New Century Arc Light Company, Limited, Iliffe-street, London, S.E.	354	12	6
Walsall Electrical Company, Limited, 57, Bridge-street, Walsall	361	13	9
Crompton and Co., Limited, Mansion House-buildings, London, E.C.	380	0	0
Johnson and Phillips, Old Charlton, Kent	382	4	6
General Electric Company, Queen Victoria-street, London, E.C.	409	14	6

Newcastle.—The Tramways Committee have accepted the following tenders: Dick, Kerr, and Co., Edinburgh and London;

Digitized by Google

1,000 tons of rails and fishplates, £6. 8s. 9d. and £12. 10s. per ton respectively; J. F. Miller, North Shields, erection of pumping station in connection with the power station, £2,668; Simpson, Newcastle excavations and laying of pipes to pumping station, about £1 681; Electrical Power Storage Company, car-sheds and storage battery, £2,117 3s.; J. H. Holmes, Shieldfield, battery for sending the electric current along the rails, £380; Veitch, Barrack-road, alterations to the Haymarket car-sheds and the Gosforth car-sheds, £5,178. 14s. 1d. and £3,646. 18s. 11d. respectively.

BUSINESS NOTES.

TRACTION.

Dundee.—The Secretary for Scotland has passed the Corporation's tramway provisional order.

London County Council Tramways.—In the House of Commons this Bill has been read a third time.

Leeds.—It has been decided to equip the whole of the Corporation tramcars with the Tidswell lifeguard.

Broadstairs.—An inspection by the Board of Trade of the town portion of the electric tramway line has been made.

Ilford.—Colonel von Donop has held an enquiry into the Urban District Council's application for sanction to borrow £106,737 for tramways.

Coseley.—The British Electric Traction Company have commenced breaking up the roads at the Fighting Cocks to lay down the electric tramway system.

Lowestoft.—The Town Council have approved a draft agreement with the National Electric Traction Company with reference to the proposed electric tramways.

Northfleet (Kent).—The British Electric Traction Company have commenced the work of construction in connection with the proposed local electric tramway scheme.

Cleator Moor.—The District Council at a special meeting have decided that a petition be presented to the House of Lords against the West Cumberland Electric Tramways Bill.

East Molesey.—With regard to the London United Tramway Company's scheme for the district, the Council are advised there will be no difficulty in obtaining 40ft. bridges and the 9ft. 6in.

By-laws.—The by-laws and regulations of the East Ham Urban District Council tramways, the Bolton and suburban tramways, and the borough of Bolton tramways have now been published.

Motor Vehicles for Heavy Traffic.—There are rumours of the formation of a strong company having for its object the popularising of the heavy motor wagon for ordinary purposes of commerce.

Private Bills.—In the House of Commons the following Bills, received from the Lords, have been read a second time: Chester Corporation Tramways, South Lancashire Tramways, and Tyneside Tramways and Tramroads.

Birmingham.—A petition praying to be heard has been deposited at the Private Bill Office of the House of Commons against the Birmingham (City) Tramways on behalf of the Handsworth Urban District Council.

Stockport.—It having become necessary to widen the Tiviot Dale end of Heaton-lane for tramway purposes, an agreement has been arrived at between the Corporation and property owners by which the property will be set back.

Taunton.—In further reference to the strike among the men engaged in preparing the roads for laying the lines for the proposed electric tramways, the men resumed work last week, having accepted the contractor's offer of 5d. per hour.

Sedgley.—The British Electric Traction Company have given notice to the Council of their intention to commence work on the Sedgley section of the tramway at two points, the first working towards Coseley and the second towards Sedgley.

Beverley.—The town clerk has been requested to enquire of the North Eastern Railway Company whether they desire to work the North Holderness light railway by electricity, assuming terms could be arranged with the Council for the supply of the same.

Auchland.—The Urban District Council have agreed, in respect to electric trams, to extend the time of agreement with the promoters of the scheme to 42 years, on the understanding that the streets belonging to the Council included in the scheme are paved with wood blocks.

Nottingham.—Another step in the electric tramway undertaking has just been entered upon by the commencement of work on the Trent Bridge section. On the Bulwell section the work is being pushed vigorously forward, and in a few weeks it is hoped that cars will be running.

Manchester.—The receipts from the first day's running of the electric cars between Albert-square and Cheetham-hill and Hightown amounted to £166 19s. 7d. The Corporation have decided to petition against the Manchester-Liverpool Electric Express Railway Bill in the Lords.

Glasgow.—We understand that good progress is being made at the Pinkston power station. The first American engine has been supplying power for the cars for some time, and the second engine is now in complete working order, so that an increased service of electric cars is to be given.

West Bromwich.—The Corporation have completed the arrangements for the purchase of the portion of the tramways belonging to the South Staffordshire Company within their district, and the same will be transferred shortly and worked by electricity under the control of the municipal authority.

Rochdale.—The actual construction of the new tramway lines of the Corporation has been commenced on the Norden section. The ceremony of "breaking the ground" was performed by the Mayor, accompanied by several members of the Council and the borough electrical engineer, Mr. C. Atchison.

Batley.—The Town Council have decided to apply to the Board of Trade for a prolongation of the time allowed for the commencement and completion of the works authorised by the Batley Tramways Order of 1900 to Feb. 6, 1902, in the first instance, and Aug. 6, 1903, in the second respectively.

Morecambe.—At the last meeting of the Urban District Council a letter was read from Messrs. Heape and Ledworth, who proposed to seek parliamentary powers to convert the present horse tramway at Morecambe into an electrically-propelled system. The communication was referred to the Electric Lighting Committee.

Sunderland.—At a meeting of the Tramways Committee called for the purpose of considering the question of extensions, it was stated that it would cost £5,000 to alter the road levels, and it was agreed that a joint meeting of the Tramways and Highways Committee should be held to settle the cost between the two.

Pontypridd.—The Tramways Order Confirmation Bill, the object of which is to authorise the Urban District Council to construct electric tramways in the district, came on before the House of Lords Examiner for proof of compliance with Standing Orders. The Bill will be reported for second reading in due course.

Automobiles.—The Automobile Club, feeling that the dust raised by fast motorcars constitutes a more serious annoyance to other users of the public roads than mere quick travelling, has, we understand, offered a prize of 100 guineas to stimulate inventors to devise some means by which this objection may be obviated.

Hampton Wick.—It was stated at the last meeting of the District Council that no definite information could be obtained as to the date of the commencement of the construction of the tramway lines along the Hampton Court and Upper Teddington roads. At the present time the company are constructing the Ealing section of the line.

Edinburgh.—A meeting of the Lord Provost's Committee has been held, at which the letter of the tramway lessees regarding the discontinuance of the circular route was again under consideration. A draft reply was generally approved, and it is understood that the committee ask the tramway lessees to resume the circular route service.

Glasgow Automobile Movement.—A meeting under the auspices of the Scottish Automobile Club, Edinburgh, was held in Glasgow this week, when a resolution was unanimously adopted that a Glasgow and West of Scotland section of the Scottish Automobile Club, affiliated to the Automobile Club of Great Britain and Ireland, be formed forthwith.

Bristol Tramways Co.—We are informed that the directors of this Company, having decided to issue the further 25,000 4 per cent. cumulative preference shares created at the last general meeting of shareholders, have given to registered holders only of the Company's debenture stock, preference, and ordinary shares the privilege of applying for the new shares at par.

Worthing.—The Town Council had the proposition before them at a special meeting last week that application be made for a provisional order authorising the construction of electric tramways or light railways in the borough and adjoining parishes. A numerously-signed memorial against the proposal was present. Ultimately the consideration of the matter was deferred.

Darlington.—The Town Council have decided to apply to the Light Railway Commissioners for an order authorising the Council to construct and work or to contract for the construction and working of light railways in Darlington in substitution of the present tramways. A public meeting has passed a resolution in favour of a plébiscite of the town being taken on the question of the tramways.

Nelson.—At the last meeting of the Town Council, the Deputy Town Clerk reported the payment of the purchase money and interest to date for the Nelson portion of the tramway undertaking. The Borough Surveyor submitted his report on the repaving of Manchester-road with wood or granite in connection with the reconstruction of tramways, and the consideration of the matter was deferred for a month.

Warrington.—The agreement between the Corporation and the Warrington and Northwich light railway has been concluded. By it the Corporation have secured the option of purchasing railway No. 1 at cost price, plus 5 per cent. for supervision, and the cost of incidental works authorised by the order. The agreement also provides that the promoters shall take electric power from the Corporation with a minimum consumption of 200,000 units per annum.

North Metropolitan Scheme.—The application of the North Metropolitan Tramways Company to the Light Railways Commission for an order authorising the construction of a network of tramways, to be known as the Tottenham, Walthamstow, and Epping Light Railways is being strenuously opposed. Both the Wanstead and Woodford District Councils object to the scheme, and a resident committee is busy drawing up petitions of protest and convening public meetings.

Post Office Motorcars.—An experiment was successfully made on Tuesday by the Liverpool postal officials in carrying the mails

Digitized by Google

between that city and Southport by a motor vehicle. At last week's trials the representatives of the Post Office were greatly impressed with the utility of the motor carriages for roadwork, and it was decided that further experiments should be conducted to test the value of the vehicles for mail carrying purposes. The Liverpool postmaster will report to London on the subject.

Cardiff.—At the Town Council meeting on Monday objection was taken to the lowering of the roads under the railway bridges in order to be able to run double-decked electric cars, the Board of Trade demanding a distance of 6ft. 6in. between the roof and the bridge, on the ground of the great expense which this course would involve. The Tramways Committee's report on the subject was referred back for further consideration. It is stated that tenders for 2,000 tons of rails will be confined to manufacturers in this country.

Newport (Mon.).—At Tuesday's meeting of the District Council an amendment was brought forward to the reports of the Electricity and Tramways Committee that the tramways be leased to an electrical company. The Mayor would not accept this amendment, as it was in direct conflict with a resolution already adopted by the Corporation to work the tramways themselves. The whole matter of the new power station on Corporation-road was then approved, and the tenders for construction and equipment were agreed to.

Darlaston.—The District Council have approved the plan submitted by the promoters of the Wolverhampton District Electric Tramways, Limited, showing the line to be constructed from Bilston boundary to Darlaston Green, subject to granite setts being laid in lieu of whinstone setts. As regards the section from Darlaston Green to Crescent-road, however, the Council have decided to ask the company to construct this similarly to the portion approved. A special committee has been appointed to consider the question of widening the roads and raising and widening bridges along the route.

Pemberton.—The Urban District Council have approved the draft agreement between them and the tramways company, subject to a clause being inserted to prevent the leasing or subletting of their line, and to restrict the company from first offering their light railway to any other body than the Pemberton District Council. A report of the tramways valuer, Mr. Davidson, fixing his valuation of the tramways at £7,750, so far as the district of the Pemberton Council was concerned, to be paid by the Council to the Wigan Corporation, was adopted.

South Shields.—At the last meeting of the Town Council a letter was read from the British Electric Traction Company, Limited, stating their intention of making application to the Light Railway Commissioners for an order authorising the construction and working of light railways in the district. It was resolved to write the company stating that in the event of their making application for an order authorising them to lay down lines and work the proposed tramways within the borough, the Corporation would take steps to oppose the granting of such order.

Metropolitan District Railway.—A special general meeting of the shareholders has authorised the Company to subscribe and hold shares for any sum not exceeding £200,000 towards the capital of the Brompton and Piccadilly-circus Railway, and the directors to subscribe for debentures in the Whitechapel and Bow Railway Company, and also to join with the London, Tilbury, and Southend Railway in guaranteeing interest not exceeding 4 per cent. upon any part of the debenture stock of the Whitechapel and Bow Railway, and also subscribe for shares of the same railway not exceeding half of the capital of the Company.

Wolverhampton.—At the last meeting of the Tramways Committee a letter was read from Mr. A. H. Walker, of Johnstown, U.S.A., with reference to the Lorain (or Brown) surface-contact system which is about to be put down in Wolverhampton. Personally, he was of opinion that the system is everything that could be desired but he would hesitate putting it in over an extended area until it has had a more prolonged trial than it has in Washington, where it was laid some three years ago. It would be wise to put in, say, a mile or so under proper guarantees and test it under all conditions for a year or so.

Dublin.—The Judicial Committee of the Privy Council have refused an application of the Cavehill and Whitewell Tramway Company for powers to employ electric haulage and to raise the necessary capital for supplying it in the tramway between Whitewell and the Antrim-road junction of the Belfast Street Tramway Company's system. The Lord Chancellor said that having regard to the nature, character, and extent of the changes sought to be made in the existing order, and having regard also to the fact that the local authorities opposed, the committee thought it right to leave those who desired the change to proceed in the ordinary way. The application was accordingly refused.

Hackney.—The General Purposes Committee consider that the routes of the proposed North-East London and the City and North-East Suburban electric railways, as amended so as to provide for the line crossing Hackney Marshes to be constructed in tube, will afford great facilities for traffic; tend to decrease the at present overcrowding of the trains during the early morning and evening on the North London and Great Eastern Railways, and be a great boon to the inhabitants of the district. The committee, however, are of opinion that there are many clauses in the Bills which, as at present drawn, are extremely unsatisfactory, and efforts will be made to secure amendments at committee stage.

Morley.—At a monthly meeting of the Corporation, the Town Clerk reported that he had received the draft of an order in regard to the application which had been made to the Light Railway Commissioners by the British Electric Traction Company, Limited. An order was obtained last year for the construction of certain lines within the borough, and an undertaking was given by the promoters that they would apply for an extension of those lines so as to authorise them to construct a branch from the Bottoms down to the London and North-Western Railway Station. This order appears to be the one which they are applying for to give effect to that undertaking. The matter was referred to the Electric Lighting Committee.

Birkenhead.—The Town Council have authorised the Tramways Committee in respect of the following: To provide double tracks in place of single tracks in the following streets at an estimated cost as appended—in Park-road North, £4,694; in New Chester-road, between Green-lane and St. Paul's road, £205; in Laird-street, from Park road to the car-sheds, £4 066; in Park-road South and in Prenton-road West, £1,200; and passing places in Argyle street and Hamilton-street, at a cost of £936; also to apply to the Board of Trade for sanction to borrow £13,000 for 15 additional cars; for £7,500 for extra generating plant; and for £1 000 for machinery and fittings at the north-end depôt, for effecting repairs to the rolling-stock.

Huddersfield.—According to the official returns the receipts on the Corporation tramways, when the cars were run for the first time on a Sunday, amounted to £123. 6s. 6d. This is more than the average on a Saturday or other day of the week. It is estimated that over 15,000 people availed themselves of Sunday's trams. With the introduction of Sunday labour, however, the tramcar employés are agitating for wages for Sundays at the rate of time and a half. It is said they determined last week-end to refuse to work. At a meeting of the General Purposes Committee on Tuesday the matter was under discussion, and it was moved that the men be granted time and a quarter pay, but the committee eventually left the matter in abeyance for a month.

Halifax.—A meeting of the ratepayers in the Warley road district has been held to protest against the action of the Tramways Committee in reducing the service of cars on the branch route from King Cross to West View Park. A resolution was adopted requesting the committee to renew it immediately "as an act of common fairness and equality." It will be remembered that this was one of the routes which came under, under the decision of the committee to reduce the number of cars running in different parts of the city in order to effect a saving in the weekly expenditure. The Town Council have adopted the following resolution: "That the surplus now standing to the credit of the tramways account and all further surpluses be placed to a renewals account, and that all renewals be paid for out of that account."

Wigan.—At the last meeting of the Town Council it was stated that the Martland Mill line is growing in success. Up to the end of the financial year the takings on the line averaged £75 a week. For the last two months they have averaged £98 a week. The Wigan-lane line has now been opened for public service. Negotiations are proceeding with the Wigan and District Tramways Company with a view to the Corporation taking over their lines. As regards the difficulty of selling the Pemberton line, of which notice has been given of purchase by the Pemberton District Council, a sum has been agreed satisfactory to both parties. The Wigan Corporation are endeavouring to get the consent of Parliament to a Bill to continue the Wigan line to Standish and on to the Royal Oak at Coppall, and also the extension of the present line from Martland Mill to Crooke. Instructions have also been given to the borough engineer to prepare plans for tramways down Poolstock.

New South Wales Tramways.—The Railway Commissioners of New South Wales in their quarterly statement for the three months ended March 31 last state, with regard to the tramways, that the total earnings during the quarter amounted to £151,668, an increase of £38 599. The expenditure amounted to £114,312, an increase of £28 383 the net improvement being £10,216. The number of passengers carried was 25 682 063 an increase of nearly 7,000,000 passenger fares. This advance in the tramway business is no doubt due to the popularity of the electric tram system (which is rapidly being substituted for the steam system for many years in use), and also to the effect of the general introduction of penny fares. During the quarter a new section of tramways, that to Leichhardt (a suburb of Sydney) has been converted to electric traction. During the same period an extension of 77 chains has been made on the line to Tighe's Hill, one of the suburbs of Newcastle.

Lancashire Tramways.—Although the Lancaster Corporation have refused to sell their rights to carry out an electric tramway scheme within the borough, it is reported that the syndicate in question have entered into an agreement with the Lancaster and District Tramways Company to purchase their line from Lancaster to Morecambe for £1 per preference share and 18s. per ordinary share, upon condition that the Lancaster Corporation will extend the powers of the company for an extra term of 25 years—*i.e.*, that they will promise not to exercise their powers to purchase until 1935 instead of 1910. If this power be obtained, the syndicate will convert the present tramways from Lancaster to Morecambe into an electrical overhead system of traction, using double lines. They would enter into an agreement, it is said, with the Corporation for the supply of electrical energy, and make a contribution for the widening of Skerton Bridge, over which the trams to Morecambe pass.

Hebburn.—The Urban District Council have for some time past been considering a series of proposals for the introduction of electric energy and tramways into the town, and we hear negotia-

Digitized by Google

tions are now approaching completion. Having obtained a provisional order, the authority sought to make the best terms possible with competing companies in preference to entering upon an undertaking of their own. At the present time there are four companies with whom the Council are in negotiation for the supply of electricity. Three of these have practically agreed to provide lighting and tramway facilities, while the fourth is willing to supply illumination and the necessary energy for the trams. There is a feeling that it would be desirable to have a through service between Gateshead and Shields, and this may not be accomplished if a tram service for Hebburn alone is established. In the meantime the authority have asked the companies to furnish amended conditions on one or two vital points, and when these have been received and considered a final decision will be come to by the Council.

Gateshead.—The running of the electric cars in the town has so far proved a great success. All the routes have not been opened, but the Low Fell, Sunderland-road, and Teams lines, which are running, are extensively patronised. Nevertheless, a petition signed by 1,084 residents of Coatsworth-road and district, protesting against the charges of the tramways company, has been presented. The Parliamentary Committee of the Town Council have received a report from the Board of Trade inspector relative to the danger from falling trolley wires. It stated that both he and the town clerk had grasped the wires and had hardly felt any shock. In wet weather the shock might be greater than on the fine day in question. Under ordinary circumstances, he stated that a shock at 500 volts was more unpleasant than touching a kettle of boiling water, but not so painful as touching a red-hot poker. Unless an extensive and prolonged contact were made, it would not be dangerous. It was possible that a falling trolley wire might cause an accident. It would, no doubt, kill a horse. A simple device might be employed to cut off the current, but he was not prepared to recommend its use.

Motor Traction Co.—The half-yearly meeting of this Company was held on Monday, when the report of the directors was presented, which stated that the two motor-omnibuses which for a considerable time were running between Kennington and Oxford-circus were withdrawn in December last, the directors having come to the conclusion that all the experience that could be got from the working of these vehicles had been gained. The improved omnibuses ordered from the Daimler Company of Cannstatt were expected to be delivered in March, but, owing to certain alterations deemed necessary, some delay has occurred; delivery, however, is promised in a few weeks. In the early part of the present year the factory buildings were so far completed as to admit of work being commenced in a portion of the premises. The additional machinery required is being put down as quickly as possible, and the Company will soon be in a position to undertake the construction of motor vehicles of the most approved type. A large space being available for storage purposes at the depôt, the Company is now prepared to house, repair, and keep in order any description of motorcar, and has special facilities for charging electric cars and for the sale of petrol spirit.

Wakefield.—The report to the Board of Trade by their inspector, Lieut.-Colonel Donop, on the question of running the proposed tramway or light railway over Wakefield Bridge has been communicated to the promoters of the scheme and to the local authorities concerned. Colonel Donop is distinctly favourable to carrying the line over the bridge, to which objection had been raised on the ground of its narrowness and insufficient strength. He sees no reason why the light railway scheme should be hung up pending the decision of the local authorities as to exactly what steps they are going to take with regard to the widening. We understand that the promoters are now seeking further powers at the hands of the Light Railway Commissioners, having applied for an order to connect Ossett with Horbury, which, in turn, is to be connected with Wakefield, and to lay a tramway from Wakefield to Lofthouse, Rothwell, and Hunslet, there to join the Leeds Corporation tramway system. It is expected that the East and West Yorkshire Union Railway Company, who have already obtained powers to construct a passenger line between Rothwell and Leeds, will have something to say on the matter when the local enquiry is held.

Newcastle.—A detailed report as to present expenditure and the prospective cost of the electric trolley system of tramways now being laid down by the Corporation states that when the parliamentary powers were first obtained the total estimated expenditure was £614,250. It is now estimated that it will amount to £803 281. The chief causes of the rise are put down to the increased cost of generating plant and trolley wires owing to the advance in materials, the cost of the tramcars, in the purchase of property of the old company not originally contemplated, and involving payment of £34 000, and £6,450 for arc lamps provided at the request of the Watch Committee for street-lighting. The only portion of the undertaking which is likely to remain within the estimates is the track. The sum of £400,000 was estimated for this, but it is now stated that £325 000 will suffice. Mr. Mordey, of the firm of Messrs. Mordey and Dawbarn, of London, has prepared a report for the Corporation upon the supply of electrical energy within Newcastle, the concluding remarks of which are: "The Corporation can never again have such an opportunity as the present for a satisfactory rearrangement. It seems to us that it would not now be difficult to take the matter up, aiming at a general supply by (1) the development of the existing stations within the municipal area, making full use of the new tramway station; (2) unification of the system over the whole area; (3) interconnecting, so that one station only could supply all needs during periods of light load." The Town Council have appointed a sub-committee to consider the report fully, and to prepare such form of communication as they might consider desirable, to be sent to the Board of Trade. The City Council have sealed the following document: authority to the Public Works Loan Commissioners to deliver certificates for £50,000 (part of the loan of £350,000 for tramway construction) to the city treasurer.

Sheffield.—With reference to the recent trouble with the tramway men, the following report of the Tramways Committee appears in their minutes: "The committee have investigated the cause of the recent threatened strike in connection with the dismissal of Mr. G. E. Francis, the car-sheds superintendent. As a result thereof, they are glad to find that it originated only with a few fitters, car washers, and labourers directly under the control of Francis. The committee summoned before them all the men who had taken part, and requested them to give explanations of their conduct. Nearly all the men concerned in it having expressed their regret at the action they then took and promised not to offend again, the committee recommend that no further action be taken against them, with the exception of four men, with regard to whom it is recommended that one week's wages in lieu of notice be given to them to terminate their engagement." The accounts of the Corporation tramway undertaking for the year ended March 25 last show that the number of passengers carried was 34,370,763, as compared with 19 209,714 the preceding year. The receipts were: horse traction, £27 494; electric traction, £108 300—making a total of £135,794. The gross profits are £48 657, and after deducting interest and sinking fund a net available profit of £21 817 remains. It is proposed to place £15,000 of this to a special fund to provide for renewals, bringing the surplus account to £51 277. The rates have now been relieved from the proceeds of the tramways working to the extent of £22,000. The total street mileage is now 22, and the receipts are constantly growing. In Whit-week they amounted to £4,590, or nearly £1,000 in excess of the Easter takings. The Tramways Committee have under consideration the question of laying tramrails up Glossop-road, thus providing an alternative route to Broomhill. The doubling of the rails in Church street and West-street is to be taken in hand at the earliest possible moment. Rapid progress is being made with the work on the Intake route—from the cemetery to Intake village. There is likely to be some delay in regard to the extension from Heeley to Norton Woodseats, considerable difficulty having arisen as to the widening of the road from Woodbank-crescent.

London Underground Railways.—The Joint Committee of both Houses of Parliament appointed to consider the proposed routes in various Metropolitan Underground Railway Bills, now before Parliament, continued their enquiry on Tuesday. Mr. H. B. Palmer, traffic superintendent, put before the committee his views as representing the Metropolitan Railway. He did not consider the proposed loop at the end of the Central London line was necessary, and the advantages of such a loop were more imaginary than real, and disproportionate to the cost. The Metropolitan Company had not realised the advantages they had hoped to gain from the adoption of the circle in place of the horseshoe service. It would be cheaper and more convenient for the Central London Company to add to their line by about a train's length, and put in a cross-over road from up to down line. By this means a service of 30 trains an hour could be kept up, and by adding another coach to their trains the Central London might increase their carrying capacity by 33 per cent. Such was the experience of the Paris railway. His view was that in the adoption of the Bank as the central point for the termini for tubular railways lay the basis of a very good solution of the problems of London traffic. The extension of the North-East London line from Liverpool-street to the Monument was not necessary in the public interest, and it would be merely parallel to the Metropolitan route. His view was that it was undesirable to run tubes through the central district. For public convenience these tube railways should lead to and from a common centre, with exchange stations at convenient points to communicate with main lines of railway. Delays and irregularities in service would in that way be less likely to occur. If a tube railway had a through route, say from Tottenham and Walthamstow to Charing Cross and Hammersmith, a breakdown at the Charing Cross and Hammersmith end would dislocate the traffic throughout. In answer to the Chairman, the witness said that with the adoption of electric motive power his company would be able to increase the service on both the Inner Circle and suburban connections. Mr. Thomas addressed the committee on behalf of the Metropolitan Railway Company, disclaiming any attitude of general hostility to tubular railways, but claiming for the company that they should be allowed to keep the traffic they had secured by the facilities they offered, and which they were prepared to increase to meet public demands. Mr. G. Dew, alderman of the London County Council and member of the Housing Committee and secretary to the Central Association for the Extension of Workmen's Trains, gave evidence from the point of view of the housing question. The means of transit on many of the suggested railways were so fragmentary, dealing only with such small sections and touching such small districts of inner London, that they would offer little assistance towards the solution of the housing question. A complete scheme must start from a central point where workmen wish to arrive in large numbers and thence run into the outer suburbs, taking in not only the densely-populated parts of inner London, but going to the leaner and undeveloped districts. After consultation, the committee decided to confine evidence for the present to the question of route. The committee adjourned.

Digitized by Google

LIGHTING AND GENERAL.

Levenshulme.—A destructor scheme is being discussed in committee.

Leith.—The salary of Mr. J. G. Scott has been increased by £50 per annum.

Bangor.—Application is to be made for sanction to borrow £2,000 for new cables.

Montrose.—The Town Council have decided to erect electric lights in various streets.

Colne.—Arrangements are being made for an electric light installation at the new market.

Aylesbury.—The Electric Lighting Committee are offering £600 for a site for the electric lighting works.

Accrington.—The Corporation have decided upon an expenditure of £9,000 for electric lighting extensions.

Clyde Valley.—The Clyde Valley Electrical Power Bill has been read a second time in the House of Commons.

Tenbridge.—The 113 tenders received for the electric light installation have been referred to Mr. Hammond.

Share Market.—Little was done in electric shares during the week, but there was a good demand for debenture issues.

Stockton-on-Tees.—The Town Council have decided to apply for sanction to borrow £27,500 for electricity works extensions.

Blackburn.—The Electricity Committee have decided to reduce meter rents to 2s. a quarter for all sizes up to 50 amperes.

Southend.—The surveyor is about to prepare a scheme and estimate for the provision of a destructor at the London-road depôt.

Trowbridge.—Mr. David Stevenson has been appointed to undertake the planning and supervision of the proposed electric lighting.

Dudley.—A suggestion that the electric light should replace the gas at the baths will shortly come before the Estates Committee.

Northfleet.—The Bill authorising the provisional electric lighting order has passed through the unopposed committee of the House of Commons.

Guildford.—The Council have decided to advertise in the technical papers for schemes to work their provisional electric lighting order.

Chesham.—The Urban District Council are conferring with the High Wycombe Electric Lighting Company as to the sale of their provisional order.

South Bank.—The Urban District Council intend to petition in favour of the Cleveland and South Bank Electric Power Bill in the House of Lords.

Morecambe.—The last account of the Electric Light Committee shows a net loss on the year's working ending March 31, 1901, of £667. 9s. 9d.

Electric Hoists.—We understand that an order has just been issued for electric hoists to be fitted to all British warships that carry guns in casemates.

Middlesbrough.—The last report shows that there are now 8,681 lamps supplied, and applications for 3,498 are in hand—making a total of 12,179.

Monmouth.—Transformers and cables are to be provided for supplying electric light to the grammar school and the high school, at a cost of £400.

Perth.—It has been remitted to Mr. Hawbayne to make enquiries and report as to the advisability of taking an electric main to the Barnhill district.

Newcastle-on-Tyne.—The inauguration of the electric power supply on Tyneside will take place on June 18 by Lord Kelvin. Sir Andrew Noble will preside.

Winchester.—The Council's application for power to raise the sum of £2,850 by loan for extension of electric light cables in certain streets has been approved.

Stroud.—The report of the engineer respecting the scheme of electric lighting for the town is now before the Lighting Committee of the Urban District Council.

Brierfield.—The Burnley Town Council have offered to supply the Urban District Council with current at 5d. per unit, provided 30,000 units per annum are guaranteed.

Fulham.—During the fortnight ended June 1, 1901, 1 292 loads of refuse have been destroyed, 24 loads of clinker sold, and 365 tons of clinker had been barged away.

Waterford.—The county borough of Waterford, Ireland, have retained Messrs. Lacey, Clirehugh, and Sillar to furnish them with a report on the electric lighting of the town.

Hackney.—At the meeting of the Borough Council last night it was recommended to consider schemes for cheap slipper baths in connection with the electric light undertaking.

Ayr.—The Council have decided to lay a 2in. pipe from the cable trench to every centre pole for lighting purposes. This will be an extra charge by the contractor for the roadway.

Hartlepool.—The Corporation will at their next meeting consider the electric lighting of the borough. The cost of the necessary plant, etc., is expected to be about £18 000.

Kingstown (Dublin).—A special meeting is to be held to consider the tenders for electric lighting plant, and application is to be made for sanction to borrow £50,000 for the scheme.

Eastbourne.—The Council have decided to charge the Devonshire Park Company 5½d. per unit for electric light supplied during the nine months the municipal orchestra play in the park.

Bath.—The Electric Lighting Sub-Committee have recommended the Corporation to confirm, as a permanent engagement, Mr. F. Teague's hitherto temporary appointment as borough electrical engineer.

Broughty Ferry.—At Tuesday's meeting of the Town Council a motion to the effect that the minute, so far as regarded the purchase of a site for electric light purposes, be rescinded, was agreed to.

Provisional Orders.—The Board of Trade have granted an electric lighting order for the Monkseaton and Whitley district. The Hucknall Torkard Urban District Council are about to apply for an order.

Removals.—The registered offices of the Hove Electric Lighting Company, Limited, and the Calcutta Electric Supply Corporation, Limited, have been removed to Salisbury House, London-wall, E.C.

Clayton.—The District Council have accepted the report on the interview between the sub committee representing the Clayton and Harwood Councils and the Board of Trade on the subject of the electric lighting order.

Worthing.—The Electric Lighting Committee have directed the resident engineer to prepare the necessary specification for the wiring of the electric generating station, and tenders are to be invited for carrying out the work.

London Gazette.—June 27 has been fixed as the last day for receiving proofs in the estate of Mr. A. W. Hirst (trading as Hirst and Co.), Croydon. Mr. A. Mackintosh, 24, Railway-approach, London Bridge, S.E., is official receiver.

Camberwell.—Notices have been received by the Borough Council from the County of London and Brush Provincial Electric Lighting Company of intention to construct a transformer box and to lay mains in Elm-grove and Chumleigh-street.

Keighley.—The Town Council have, after considerable discussion, confirmed the action of the Gas and Electricity Committee in opposing the application of the Fleece Mills Company for powers enabling them to generate and supply electricity generally.

Wakefield.—The salary of the electrical engineer (Mr. Blackmore) is to be advanced to £300 a year, and also, in consideration of the supervision of the extension of the plant, a bonus of 1 per cent. will be paid to him on all completed work on capital account.

Woolwich.—We have already noted that the Council have decided to purchase the existing local electric light undertakings at a cost of about £100,000. At Plumstead the Council are inaugurating their own system of electric light at a total cost of £200,000.

Walsall.—The Electric Lighting Committee have approved of part of the corporate land fronting Freer-street, forming part of the pig market, with the building thereon formerly used as a weights and measures office, as a site for the new transformer sub-station.

Pemberton.—The Council have asked the architect to press the contractors of the station buildings. The electrical engineer is to report to the next meeting as to the number of additional arc lamps required. The Council intend to discuss the question of wiring at an early special meeting.

Brighton.—The Guardians have accepted an offer from Mr. P. Coote, electrical engineer, Brighton, to prepare a specification for wiring the workhouse buildings. An advertisement is to be issued inviting tenders to wire the above-named buildings in accordance with such specification.

Concealed Wiring.—We notice that Mr. J. Bathurst, of the Conduit and Insulation Company, Limited, is just about to start for the United States with the intention of visiting the Buffalo Exhibition in order to see the latest American electrical practices, particularly in respect to wiring developments.

Stafford.—On Tuesday plans were approved for the electrical testing and packing shops, boiler-house, smithy, machine shops, ironfoundry, sawmills, carpenters' shops, brassfoundry, and offices, covering an area of something like 18,000 square yards at the Hough, by Messrs. Siemens Bros. and Co., Limited.

Aspull.—The Lancashire Electric Power Company have asked the Council for an early interview with reference to the supply of electric current in bulk. The clerk has been instructed to reply that the Council thought it too early for the interview, but if the company still wished for an interview one might be arranged.

Mines Drainage and Electrical Pumping.—At the last meeting of the Mines Drainage Commission at Dudley, the Chairman (Mr. Cochrane) said about November next they would be in a position to introduce electrical surface pumping. They proposed to erect an electrical station at Leabrook, and to introduce Mond gas at Tipton.

Swinton and Pendlebury.—The Tramways and Electricity Committee have asked the Salford Corporation upon what terms the Corporation would be willing to supply electricity in bulk to consumers in the Swinton and Pendlebury district for a definite period, and also when it was probable the work of relaying the tramrails would be completed.

Swansea.—During the past month 117 applications were received for the supply of electrical energy, being equal to a demand of 13,748 c.p. As to lighting the docks, it has been decided to submit to an independent expert the question at issue between the Corporation and the Harbour Trust as to what the electric lighting actually costs the Trust.

Digitized by Google

Hastings.—The electric light mains are to be extended at a cost of £190, and application is to be made for sanction to the borrowing of the total estimated cost, and of £103. 10s., being the estimated cost of the provision, erection, etc., of the three electric arc lamps ordered at the last meeting of the Council to be placed in the western portion of Norman road.

Chesterfield.—The Town Council have decided to buy an additional boiler for the generating station, in view of the large demand for electric lighting in the borough, and to obtain an additional 200 kw. set of machinery for the generating station, at the estimated cost of £5 000. Application is to be made for sanction to a loan of £6,000 to carry out the proposal.

Redditch.—At the last meeting of the Urban District Council it was proposed: "That, owing to the large and increasing expenditure upon the electric lighting scheme, it is desirable that the Council shall obtain further expert advice upon the undertaking." After a long discussion, it was decided to defer the question until the new generating plant is put down and got in working order.

Shrewsbury.—At a special meeting on Tuesday, the Lighting Committee presented a report recommending the extension of the electric light mains at a cost of £420 and it was also decided to apply for sanction to raise a loan of £16,526 for the extension of the works, and, if possible, to obtain further time for the repayment of all the money borrowed and spent upon the undertaking.

Winsford.—The Board of Trade have explained to the Urban District Council that they had no power to grant an extension of time for the lighting order. The Board also intimated that the undertakers did not appear to have any present intention of giving effect to the order, and it would devolve upon them at the expiration of the time to consider the question of revoking the order.

Ormskirk.—At the last meeting of the Urban District Council, a letter was read from Mr. W. J. Herring, general manager of the Lancashire Electric Power Company, requesting an early interview with the Council in reference to the supply of electric current in bulk to the district by the company. A sub-committee, consisting of Messrs. Walker, Ellis, and Knowles was deputed for that purpose.

Elland.—The attempt to secure the public ownership of the Elland-cum-Greetland gasworks not having been successful, the District Council are seeking to make use of the provisional order to generate and supply electricity, granted nearly two years ago. The Electric Lighting Committee have at the present time under consideration a scheme which is estimated to entail an outlay of about £10,000.

Carnarvon.—The Town Council have decided to apply for an electrical lighting order for the borough, leaving the question to be decided later on whether they themselves or a company under their authority should carry out the works and supply electricity. This step is taken in consultation with Sir W. H. Preece, who kindly promised his gratuitous assistance in the matter, as a freeman of the borough.

Luton.—Mr. Snell has informed the Council that everything is ready for the supply of electric light by June 20, 1901. Mr. W. H. Cooke enters upon his duties as resident electrical engineer from June 1, but Mr. Snell is not relieved of his duties and responsibilities as the electrical engineer for completing the installation. The Council have declined an offer as to free wiring by the National Electric Wiring Company, Limited.

Peebles Hotel Hydropathic.—A new wing has been erected at a cost of £5,000. All the latest appliances from Continental health resorts have been introduced, including static electricity with ozone apparatus attached, such as is in use at Baden and Homburg. An apparatus has also been fitted up for the "bullseye" electric treatment by the use of coloured rays of light applied to various parts of the body, and electric light has been installed.

Batavia.—The *Bulletin Commercial* states that Messrs. H. R. der Mosch and H. Jul. Joostenz of Batavia, have obtained a concession to work, etc., for 30 years an electric light and power supply for the towns of Padang and Djokjakarta. Padang is the most important town on the west coast of Sumatra, and has a population of about 35 000. Djokjakarta has 85,000 inhabitants, and is connected by railway with the town of Samarang.

Colwyn Bay.—A further loan of £8,450 is to be applied for to provide for extensions of the main along the Conway and Abergele roads, as well as a new distributor to Colwyn Bay Hotel and Penrhos College. The Council intend to ask the Local Government Board not to set these loans against the Council's borrowing powers, as the electric works were of a permanent character in the same way as the gas undertakings.

Bury.—The last report of the electrical engineer shows that during the month ended May 19, five additional consumers with 95 8-c.p. lamps were connected, and extensions amounting to 652 8-c.p. lamps were made on existing consumers' premises, making a total of 747 8-c.p. lamps, as compared with 471 8 c.p. lamps for the corresponding period of last year. The cables are to be extended down Manchester-road as far as St. Peter's Church.

Linlithgow.—At the last meeting of the Town Council a communication was read from Messrs. Crompton and Co., enquiring what had been done by the Council in regard to their offer to introduce the electric light to their town, and offering to apply for a provisional order in their own name. The letter was remitted to the Lighting Committee, who are to submit a report of the whole question to an early meeting of the Town Council.

Dissolution of Partnership.—Messrs. Nicholson and de Winton have by mutual consent dissolved partnership as and from March 30, 1901. Mr. F. B. Nicholson, M.I.E.E., will continue to carry on the business of the firm under the style of Nicholson and Co., at 53, Victoria-street, as heretofore. All moneys due to and owing by the late firm will be received and paid by the said F. B. Nicholson. Mr. W. H de Winton, A.I.E.E., will carry on business on his own account at 53, Victoria-street, Westminster.

Cupar.—Figures showing the cost of incandescent lighting and of the electric light, the difference in favour of the electric light being about £130 per annum, having been submitted to the Lunacy Board last week, it was proposed to introduce an electric lighting installation into the asylum, in accordance with the report recently before the Board. The motion, however, was withdrawn, and it was agreed that the matter should be left over until the Board had before them the plans for the addition to the building, when the whole matter would be gone into.

Wolverhampton.—On Monday a report was adopted giving an abstract of the accounts of the electric lighting undertaking for the year ended March 31 last. The result of the year's working has been a loss of £130. 16s. 6d., arising principally from a slight reduction in the charges. If the same charges had been maintained the committee would have made a profit of between £3,000 and £4,000. Last year the consumers benefited by the reduction to the extent of nearly £1 200 During the year the quantity of electricity generated was 850,173 units.

Electric Fans.—We have received from Messrs. J. Gibbs and Son, 72, Duke-street, Liverpool, a copy of a letter from Mr. B. H. Bedell, engineer of the Electric Timber-Seasoning and Preservation Company, Limited, speaking in eulogistic terms of three fans which were supplied by Messrs. Gibbs more than six months ago, and which had been running continuously night and day almost ever since, and stating that the fans were keeping cool, were running sparkless, and were taking now even a smaller current than that which they took when tested at the works.

Southwick.—In consequence of the refusal of the Council to entertain the idea of the Brighton Corporation erecting overhead telephone wires in the district, a deputation from Brighton waited upon the Southwick Council. Subsequently the Council resolved to grant the Brighton Corporation leave to construct certain telephone circuits in the district, provided that all lines crossing tramway wires be taken underground, and also provided that the maximum charge in the district be £5. 10s. each instrument, and in any case not more than will be charged in Brighton.

Worcester.—The Council have approved Mr. Rowe's plans of the proposed Tybridge-street generating station, and have instructed him to prepare a detailed specification and obtain tenders for the work. The electrical engineer is to complete the engineering plans of the machinery and plant for the new station as quickly as possible. Application is to be made for sanction to a loan for building and equipping the new station, amounting to £30,450, on the understanding that the amount of the loan be revised in accordance with the amounts of the tenders when received.

Stock Exchange.—The Stock Exchange Committee have appointed June 19 special settling day for the West London and Provincial Electric Supply Company, Limited 9 891 ordinary shares of £1 each fully paid, Nos. 7.501 to 11,425, 12,926 to 15,025 and 16,026 to 19 891, and 34,314 6 per cent. cumulative preference shares of £1 each fully paid, Nos. 7 501 to 36 045 and 36,146 to 41 914 The committee have ordered to be quoted in the official list Edmundsons' Electricity Corporation, Limited, 6,637 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 1 to 6 637.

Dumfries.—At last week's meeting of the Town Council the Electric Light Committee reported that they had found it impracticable to proceed with the scheme of utilising water power for the generation of electric light, according to the report of Mr. Ritchie, electrical engineer. It was decided that the clerk should communicate with Dr. Mond on the subject of the suitability of the new Mond gas for electrical power, and to write to the Board of Trade explaining the Council's position in regard to the provisional order, and asking an extension of time in order to carry it out.

Sheffield.—The accounts of the Corporation electric supply department for the last fifteen months show a total income of £41,939, being an increase of £18,597 over the previous year. The expenditure has been £15 985, and after deducting all interest charges, and allowing for sinking fund, there is a profit of £4,048. The opposition to the Yorkshire Electric Power and the Derbyshire and Nottinghamshire Electric Power Bills in the House of Lords is to be confirmed. The salary of Mr. S. E. Fedden, the chief engineer and general manager of the department, is to be increased by £100 per annum. Land is being purchased near Old Park Wood for the erection of a new electric power station.

Personal.—Mr. L. Paton Greig, formerly of Edinburgh, has been appointed chief electrical engineer to the Bury St. Edmunds electric lighting works, in succession to the late Mr. A. H. Roe, who was appointed to the position on the inception of the electric lighting scheme in Bury. Mr. Greig received his technical instruction in electrical engineering at Heriot Watts College, Edinburgh, and completed it at the Edinburgh electrical works, subsequently receiving an appointment as assistant inspector of mains in the city. After three years' service he was appointed electrician in charge of a portion of the works at Bradford, Yorkshire, and subsequently was appointed assistant engineer at Bury St. Edmunds. His present position is worth £150 a year.

Digitized by Google

Hereford.—The Urban District Council have borrowed £6,798 from the Prudential Assurance Company at 3¾ per cent., to defray the initial outlay in connection with their electric light installation. The cables are to be laid as soon as possible to prevent the town being in darkness. The gas company have cut off the supply of gas to the street lamps.

Cheltenham.—The borough electrical engineer (Mr. Hamilton Kilgour) is busy with improvements in the plant both for lighting and traction work. The two 100 kw. alternators have been removed and the engines altered to drive two 170 kw. traction dynamos; two small 30-kw. alternators have been replaced by two 48-kw. exciters; two Babcock and Wilcox boilers and another Parsons turbo-alternator will shortly be erected. About 200 new arc lamps and a number of private lighting extensions are being provided for. About 11 miles of new cable has been laid during the last four weeks.

Yarmouth.—The accounts of the past year's working show an income of £7,225, working expenses at £5 406, leaving £1,819 to pay interest and sinking fund, and as these, with other small items, amount to £2,570, there is a deficiency of £751. This sum will not fall upon the rates, as there is a balance from previous year of £371, and a sum of £380 will be carried forward to next year's account. This result has been caused by the high price of coal, which made the production more costly by about £650, and the reduction in price to customers—made before coal was increased in price—amounting to £900.

West Bromwich.—At a recent special meeting of the West Bromwich Tradesmen's Association the following resolution was passed: "That in the opinion of this association the Electric Lighting Committee has not carried out its compact to supply electric light to shopkeepers at a price equivalent to that of gas at 2s. 4d. per 1,000, and the association considers the present charges for electric light will prove to be prohibitive to its general adoption by shopkeepers, and the association respectfully requests the Electric Lighting Committee to receive at its earliest convenience a deputation to represent the views of the association."

Sunderland.—The annual report of the Corporation electric lighting department states that the number of lamps connected on March 31 was 50,092, and the number of units sold during the year was 1,218,768—an increase of 43 per cent. of lamps and 90 per cent. of units on the previous year. The year's profit on the station was £7,254, or 7 per cent. on the average capital outlay for the year. The sinking fund and interest was £5 997, leaving a net balance to the credit of the department of £1,257. The enormous rise in the price of coal represented an increased cost to the station of £2,315. The total cost per unit was 3d., and the average revenue 3·25d. per unit.

Walmer.—The Joint Electric Lighting Committee have reported the suggestion made by Messrs. Edmundson's Electricity Corporation, Limited, that the two authorities should obtain a joint provisional order, and should then raise a loan of £25,000 or £30,000 to carry out the necessary works. The committee are of opinion that before the local authorities in any way pledged themselves to a scheme, the opinion of an expert should be taken as to the prospects of carrying out a successful installation for the two districts whether with or without electric traction. Enquiries are to be made from several consulting electrical engineers, with a view of obtaining a report on the question.

Longton.—Negotiations have taken place recently with the Duke of Sutherland and the Potteries Electric Traction Company with reference to the purchase by the Corporation of electricity in bulk. The committee in charge of the matter have now recommended that the terms offered be not accepted, "inasmuch as in their opinion they were higher than the cost at which the Corporation could produce the electric current themselves, and that no immunity against loss at start would be secured thereby." The committee also recommended for adoption a scale of charges for the supply by the Corporation of electricity by consumers. The Town Council have confirmed these recommendations.

Battersea.—At a meeting of the Council on Wednesday, the Library Committee reported that they had approved the electrical engineer's specification for wiring the central library, and recommended the wiring of the branch libraries as follows: Lurline-gardens, at £65. 17s. 6d.; Lammas Hall, at £65. 12s. 6d. They also reported the receipt of a letter from the Postmaster-General thanking the Council for their consent to the laying of additional telegraph wire pipes through the vaults under the footway in front of the central library, but declining to pay the sum of £50 required by the Council as compensation, and requesting the Council to reconsider the matter and withdraw the condition as to compensation.

Hoylake and Kirby.—Mr. H. P. Boulnois has held an enquiry into an application of the Hoylake and West Kirby District Council for sanction to borrow £13,500 for the purpose of extending the electric lighting of the district. A description of the opening ceremony of the works will be found in another column. The Council have already obtained sanction to borrow £27,000, but owing to the large demand for electric light they have already expended £30,000. The applications at present amount to 6,000 8 c.p., and it is proposed to erect plant and lay down mains which in the aggregate will cost £40,500, or £13,500 beyond the sum already expended. This would place the Council in a position to supply 14,000 lamps.

Hereford.—The accounts for the financial year up to March 25 have now been made up, and the results exceed the anticipations of the Electric Lighting Committee, as the net profit has been sufficient not only to pay the interest, but almost to discharge the first instalment of capital (£300), the amount to be borne by the rates being only £85. It is proposed to increase the salary of Mr. Poulton, the electrical engineer, by £25 per annum with an understanding that so soon as the financial position justifies their so doing the committee will recommend a further increase of £25 per annum. The committee in their last report state that they fully recognise the zeal and energy Mr. Poulton has shown in the management of the works, and are anxious to show their appreciation of his services.

Nelson.—The electrical engineer's monthly report shows the quantity of current sent out during the month to be 6 934 units. The electrical engineer having reported that it would be necessary to put down a new unit on the three-wire system in order to supply current for the next winter's load, the chairman, Alderman Hudson, and the electrical engineer are to visit Glasgow and Edinburgh to inspect the generating set offered by Messrs. Bruce Peebles and Co., of Edinburgh. The borough surveyor's plan for new station has been approved, and tenders are to be advertised for. Negotiations are pending with the Brierfield Council in regard to the supply of electricity to the Brierfield Council. The question of the tenders for the new generating sets has been left in the hands of the mayor, the electrical engineer, and town clerk.

Birkenhead.—The Electricity Committee have resolved to apply for permission to borrow £40,000 for the following purposes: for costs, charges, and expenses incurred in excess of amounts already sanctioned to be borrowed, £2,430; for providing additional generating plant at Bentinck street works, £11,270; for providing generating plant to supply the south end of the borough, £5,800; for feeder and distribution mains for the Rock Ferry district, £8 000; for distributing mains in other parts of the borough, £7 500; for service mains and connections, terminal boxes, etc., £3 000; for arc lamp mains, lamp-pillars, lamps, and switch pillars, £2 000. The new mains will be in Rock-lane, Rock Park, Highfield, Bebington-road, Bedford-road, Holt-hill, Queen-street, Chamberlain-street, and the connecting mains in New and Old Chester roads.

Crewe.—At the last meeting of the Electric Light Committee the borough accountant submitted a statement showing that up to March 31 the sum of £27,056. 6s. 8d. had been expended on the electric light undertaking, and that after adding other liabilities which had been incurred, there was a sum of £4,364. 15s. 8d. to be provided above the £35,970 already sanctioned to be borrowed by the Local Government Board. A thousand pounds, however, had been set aside for private lighting cables, and if this were taken into account the further sum required would be reduced to £3,364. 15s. 9d. The committee recommended that an application be made to the Local Government Board for sanction to the borrowing of a further sum of £5,000 for electric lighting purposes, the repayments to be spread over a period of 25 years. The borough accountant also reported that there was a deficiency in the electric light revenue account of £618. 0s. 9d., the expenditure for the year ending March 31 having been £1,292. 12s. 7d., and the income £674. 11s. 10d. The report was adopted.

Newport.—The questions of working the tramways by electric power, and whether the power required should be generated at the present electricity works on Friar's Field or a new station erected upon the Corporation-road site, are still being discussed. This has been before the Council for over two years, and there has been a sharp division of opinion upon the question, and it is now proposed that a poll of the ratepayers of the town should be taken upon the subject. The balance-sheet issued by the Electricity Committee shows that the gross profit upon the electric light supply last year was £2,557, but the interest and repayment of sinking fund amounts to £5,322, so that there is a deficiency to be met out of the rates of £2,765 against a net profit of £403 in the previous year. The deficit is mainly due to an increase in the coal bill by £1,774, due to high prices at which contracts were let, the increase in the coal consumption only being 160 tons. In addition, there is an increase in the interest and sinking fund account for the year of £1,663, due to the large repayments for new machinery.

Leyton.—At the last meeting of the Urban District Council it was decided to instruct the engineer to submit a scheme and estimate of the cost for the provision of two additional steam-engines, one being of the size of those now at the electricity works and one of a larger size, and four boilers with accessories. The station was opened in September, 1896, the initial outlay being £16,850, and the capacity of the station at that time was 3,000 lights. Ever since that time it has been necessary to make extensions, and on March 31 last the actual capital invested in the station was £98,032. 16s. 6d., while 51,500 lights were connected. The revenue from September, 1896, to March 31, 1897, was £499. 6s. 11d.; for the year ending March, 1898, £1,769. 3s. 2d.; March, 1899, £3,492. 12s. 9d.; March, 1900, £6,071. 16s. 8d.; and March, 1901, £8,751. 12s. 11d. This year upwards of £10,000 is expected. The charge for current up to March, 1897, was 5d. per unit, in 1898 4·61d., in 1899 4·02d., in 1900 3·95d., and in 1901 3·87d., making an average charge to the whole of the consumers for current during the past year of 3·78d.

Chiswick.—At a recent meeting of the Free Public Library Committee a letter was read from Messrs. Rawling and Co. stating that they were willing to carry out the arrangements for electric lighting in such a manner as to secure the best results. The suggested alterations would be made without cost, provided it was decided to proceed with the work forthwith. They estimated that the committee now paid about £40 per annum for gas, to which must be added an extra £4 for mantles, bringing the cost up to £44. Their estimate for electric light worked out at 945 units at 6d. per unit, and 1,170 at 4d., making the cost of

Digitized by Google

electric light per year £43. To this must be added £2 for the renewal of lamps, bringing the total cost up to £45 per annum, and the cost of installation was £45. The installation was to consist of 38 16 c.p. lights of 220 voltage, to be guaranteed, the fittings included, for three years. The Chiswick Electric Lighting Company sent an estimate for 60 or 70 8-c.p. lights, to cost, approximately, £50. Their charge for current was 6d. per unit. The matter was referred to a small committee, and the chairman and vice-chairman, to consider further and report on.

Lowestoft.—The matter of the subsidence at the boiler-house having been discussed with Mr. Hawtayne, the consulting engineer, who asked that an independent surveyor should make an examination with him, Mr. W. J. Roberts was requested to inspect the site. Mr. Roberts has now reported that the whole bed of the existing boiler has sunk bodily, about ¾in., and bearing in mind the very treacherous nature of the subsoil, he is of opinion it would be wise to guard against the foundations of the new boilers going likewise. He recommends that the new boiler bed be placed entirely to the eastward of the proposed position, and that it be carried down to the level of the raft in engine-room, this bed to be further supported by iron screw piles, tied together with iron girders embedded thoroughly in the concrete. Mr. Roberts has been instructed to prepare specifications for carrying out the work necessary. The tender of Mr. G. E. Hawes for carrying out the works at the station rendered necessary by the subsidence, and also for lengthening the flue at £307. 17s. 8d., has been accepted. The total cost of the various necessary works and building will be £1,400, and application is to be made for sanction to borrow the necessary sum.

Radstock and Midsomer Norton.—Mr. A. H. Preece, of Messrs. Preece and Cardew, has reported upon the question of the proposed combined scheme for electric lighting and power for Radstock and Midsomer Norton. According to the scheme recommended, the total horse-power installed will be about 120, and will supply electricity for the public lamps and for the average number of private lamps burning at one time. The estimated capital expenditure is as follows: Building and generating plant—building, £500; boiler, engines, dynamos, condensers, etc, £2,069; switchboard instruments, etc., £488; battery, £836; sundries, £107. Mains and overhead work—poles, cross-arms, insulators, stays, etc., £513; lanterns (lamps, fuses, etc.), £274; copper wire, £660; sundries and erection, £153; contingencies and engineering, £550; preliminary expenses, say, £250. Total, £6,400. If the mains are laid everywhere underground it will increase the capital expended to £8,500, but overhead wiring is recommended. The generating station would be situated at Old Welton Colliery. There is a railway siding allowing of coal being delivered by the railway company on site. There is also the river accessible for water for condensing the steam. It has been assumed that no charge would be made for water. The plant first installed would consist of two boilers and engines, each engine driving a continuous-current dynamo.

Dublin.—The following appears in a Dublin journal of Tuesday, with the statement that it is the full text of the letter which has been addressed to the Corporation by the Board of Works relative to the application for a loan of £254,500 for the purpose of carrying out the Hammond scheme for the electric lighting of the city: "Office of Public Works, Dublin, June 4, 1901. Sir,—I am directed by the Commissioners of Public Works to state with reference to application for loans for electric lighting purpose (£254,500), for sewage works (£820), and for private improvements (£800), that they find that the Corporation have not paid within the month allowed the instalments due on the 1st ult. on account of outstanding loans. When an application for a loan is under consideration, the ordinary rule is that such a default as that referred to puts a stay on the proceedings, but in view of the importance of the first loan mentioned, and the desirability of expediting its consideration, the Board are unwilling to apply the rule and stop the proceedings. Later on, however, when submitting the case to the Lords Commissioners of his Majesty's Treasury, it will be their duty to refer to the fact of such default having occurred, and their lordships will no doubt consider the matter in its bearing on the question of the sanction of the loan. I am, sir, your obedient servant, H. Williams, secretary. The Town Clerk, City Hall, Dublin."

Beetle.—The first report of the borough electrical engineer, Mr. W. R. Wright, shows the progress of the municipal electrical undertaking. The works were taken over from Messrs. Thomas Parker, Limited, in October, 1899, when the plant consisted of two 120-h.p. and one 250-h.p. sets, with two 250-h.p. sets on order for traction purposes. Additional mains have been laid in a number of streets. On taking over the works there were 36 public arc lights erected, which were supplied in groups of four. These have been altered to work in four groups of nine, as by that means a saving to the department was effected of the energy taken by one lamp in nine, or that taken by four lamps in the 36, or £50 per annum. Tramways in Knowsley-road, Rimrose-road, Derby-road, and Stanley-road had been fully equipped during the period covered in the report. Fifty-five cars are working on the lines, consuming approximately 2,000 units per day. Mr. Wright states that arrangements have been made with the contractors to subject the whole of the mains as laid by them, to a test, by supplying a pressure of 1,000 volts between all mains and earth, any faults being repaired at their own cost. Much trouble has been caused by the swinging of the lamps on the swan-neck brackets during storms, the swinging of the lamp causing breakage of the insulated supports or cutting of the cable and connections. The committee are experimenting with some rigid supports to be attached to all similar brackets. The apparent deficit, continues the report, of £1,800 (estimated) was due to the fact that the plant put down had been capable of dealing with a large tramway load, but only had a small load up in October last. Liverpool expected to take some 700,000 units per annum. So far this year that City had taken about 395,000, or about half, so that the plant had been practically idle for the half year. The coal bill seemed heavy, but the Corporation were buying coal in a very expensive market. As much of the plant was standing idle during the daytime, special terms had been offered to consumers of motive power. The one drawback was that the hours of serving the two classes of consumers overlapped during December and January, when it was dark at 4 p.m., and motors and light were all on together. In any case, spare plant had to be kept which could cope with this. Several consumers were applying for motor loads. The following is the number of units turned out during the year, allocated to their different headings: public lighting, 130,913; tramways, 337,061; meters, 159,495; works, 21,900; lost in feeders and batteries, 81,035—total generated, 730,404.

Cardiff.—Mr. A. Ellis has presented a report upon the charges made in Cardiff for current, in which he points out that with the change of the supply system from alternating to continuous current, and the extension of the system to the docks, there would be a large increase in the demand, especially for power purposes. The committee have adopted the maximum-demand system, but they have made numerous departures from that principle. Mr. Ellis says the prices should be fixed at an amount which would not only increase the demand on the plant, but would keep the plant employed for a greater length of time. "There is no reason whatever," the report continues, "why all working, interest, and sinking fund charges should not be paid out of the income and a substantial amount left over," either towards reduction of capital or relief of rates. As it is, the station has been working six years, and no clear profit has been made. The plant is now worked on an average of 2½ hours per day, and figures are given by which Mr. Ellis shows that if the plant were worked an average of even three hours per day a profit of £1,688 per annum could be made. To bring this about he recommended that the maximum-demand system be retained, that 7d. per unit for the first hour and 2d. per unit afterwards be charged, by which means those who used the light over two hours a day would get a considerable reduction. For power purposes the price recommended would work out at 4d. per unit for consumers who used the plant one hour per day, and 1½d. per unit for those who utilised it eight hours.

St. Marylebone.—The following report has been submitted by the Electric Lighting Committee: "(*a*) The chairman reported in relation to the Council's Bill for electric lighting order that the St. Marylebone Electric Company had made an offer as regards their opposition to the said Bill, and that he had, on behalf of the committee, entered into an undertaking in consequence of such offer, that in consideration of the withdrawal of that company's application for an electric lighting order, and of their opposition to the Council's order, and subject to clauses being inserted in the Council's Bill embodying the terms of the agreement to purchase the Metropolitan Electric Supply Company's St. Marylebone undertaking, the Council will pay to the St. Marylebone Company the sum of £500 in the event of the passing of the Council's Act and order, or of the purchase above mentioned not being completed. The chairman also reported that in consequence of the above-mentioned undertaking, the Council's Bill, having passed the second reading, had been referred to a committee of the House of Commons as an unopposed measure. Resolved, that the chairman's action be approved, and that the Council be informed accordingly. (*b*) The committee resumed consideration of the Metropolitan Electric Supply Company's application to lay low-tension armoured mains in St. Marylebone, pursuant to substituted plans numbered 6,723, dated April 1, 1901. Resolved that the company be informed that the committee now approve the works set out in the above-mentioned substituted plans, and that the Council be informed accordingly. Resolved that the Board of Trade be informed, in reply to their letter, read at the committee's last meeting, asking for the Council's observations on communications from the Metropolitan Company forwarded therewith, appealing against the Council's disapproval of the company's substituted plans above mentioned, that the committee have informed the Metropolitan Company that, on behalf of the Council, they now approve the works proposed to be executed, in accordance with such substituted plans, and that the Council be informed accordingly. (*c*) The committee considered communication from the Metropolitan Electric Supply Company with regard to the mains laid in excess of approved plans, stating the sole question now at issue is the method of laying the authorised mains. Resolved that the company be informed that in view of the committee's approval of the company's general scheme of mains as per sub-stituted plan No. 6,723, the committee do not propose further discussing the question of the extra mains, or the method of laying the mains affected by the recent police court proceedings; and that they note the company undertake to save the Council harmless against any damages directly arising from the existing works not having been laid in accordance with the approved plan; and that the Council be informed accordingly. (*d*) The committee recommended approval of notices from the Metropolitan Electric Supply Company as to laying a 5in. cast-iron pipe along the east and west sides of Marlborough-hill from Nos. 28 to 51, crossing Marlborough-hill at the boundary; also along the north-west side of Circus-road from No. 56 to west side of Wellington-road, and along the south-west side of Lennard-place from north-west side of Circus-road to 2, Lennard-place; and as to laying a 5in. cast-iron pipe along the east side of Loudoun-road from Nos. 26 to 42."

PROVISIONAL PATENTS, 1901.

JUNE 3.

11307. Improvements in overhead trolleys or collectors for electric tramway or railway vehicles. Richard Henry Wilkinson, 4, Clayton-square, Liverpool.

11308. Improvements in and relating to joints for conducting cables. Israel Holmes, Sunbridge-chambers, Bradford.

11315. The "Sparkless" regulator for electric motors. David MacKay and Henry Sclater, 5, Waddel place, Leith.

11327. Improvements in and relating to the electrical transmission of signs or sounds. Sigmund Musits, Richard Horóath de Szent György, and Etienne Hagyi-Ristic 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

11348. Improvements in syntonic space telegraphy. Oliver Joseph Lodge and Alexander Muirhead, 323, High Holborn, London.

JUNE 4.

11371. An improved guard for the prevention of the fouling of overhead wires by a trolley or trolley arm used in the overhead rolling-contact system of electric traction. Francis Joseph Hewitt and William George Dunning, 54, Gascoyne-street, Vauxhall road, Liverpool.

11408. Improvements in electric railways. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (Samuel B. Stewart, jun., United States.) (Complete specification.)

11408. Improvements in insulating supports or "insulators" for electric conductors. Albert Anderson and Johan Marinius Andersen, 11, Southampton buildings, Chancery-lane, London. (Complete specification.)

11450. Improvements in appliances for high-tensional electrical conductors for ensuring safety in case of fracture. William Henry Stewart, 6, Lord street, Liverpool.

11470. Improvements in printing telegraphs Robert Ashworth Fowden, Norfolk House, Victoria-embankment, London. (Complete specification.)

JUNE 5.

11473. An improvement in the mode of suspending or holding globes or shades for chandeliers, brackets, electroliers, or other lighting purposes. Henry Bisseker, 11, New Bartholomew-street, Birmingham.

11500. Improvements in the manufacture of chlorine and chlorides and in the production of electric energy therewith. Antonio Sansone, 70, Market street, Manchester.

11529. Improved manufacture of electric lighting, heating, and resistance bodies. Wilhelm Boehm, 111, Hatton-garden, London. (Complete specification.)

11530. Improvements in or relating to electric glow lamps or devices. Wilhelm Boehm, 111, Hatton-garden, London. (Complete specification.)

11537. Improvements in electric alarm apparatus. Christian Albert Jensen, 77, Chancery-lane London. (Corrado Zanotta, Italy.) (Complete specification.)

JUNE 6.

11545. An improved method of fixing and connecting up guard wires for the protection of overhead trolley wires used for electric traction, and means for automatically disconnecting the current supplied to the trolley wires. William Arthur Heyes and Lancelot Ovid Heyes, 20A, Millgate, Wigan.

11552. An improved automatic self-locking lifeguard for electric-propelled cars or other vehicles. Arthur Hudson, 13, Fortune-street, Manchester-road, Great Lever.

11582. Improvements in the construction of electrical measuring instruments. Edgar Isaac Everett and Kenelm Edgcumbe, 22, Charterhouse-square, London.

11584. Improvements in lightning conductors. Killingworth William Hedges, 8, Quality-court, Chancery-lane, London.

11600. Improvements in or relating to the formation of positive plates for electric accumulators or secondary batteries. Joseph Johann Heinrich Hunte, 322, High Holborn, London. (Joseph Lürgen, Germany.)

11619. A method of producing electrodes for electric accumulators. Ernst Waldemar Jungner, 18, Buckingham-street, Strand, London. (Complete specification.)

11625. Apparatus for applying plastic material to matrices, more especially intended for use in applying the paste to the grids in making secondary battery elements. The Electrical Power Storage Company, Limited, and William Henry Hanson, 47, Lincoln's-inn-fields, London.

JUNE 7.

11629. An improved lifeguard for electric tramcars. Joseph Bulman, 70, Langham-street, Walton-road, Liverpool.

11640. Improvements in trolley heads for overhead electric traction. Arthur Eustace Rooke and James Patterson, 128, Hope street, Glasgow.

11660. Improvements in wireless telegraphic signalling. Edward Cadett and Herbert Dickinson, 2, Camden-gardens, Shepherd's Bush, London.

11676. Improvements in rheostat elements or resistance boxes. Thomas Steel Perkins, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act 1883. Sec. 103 Nov. 9, 1900, being date of application in United States.)

11677. Improvements in protecting devices for the coils of electrical apparatus. Percy Holbrook Thomas, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Nov. 9, 1900, being date of application in United States.)

11702. Improvements in and relating to electric accumulators. Bernard Josef Lürgen, and the D.P. Battery Company, Limited, 18, Southampton-buildings, Chancery-lane, London.

11703. Improvements in electrical distribution boards. Charles Grundy, 18, Southampton-buildings, Chancery-lane, London.

11707. Improved construction of contact maker or current conductor for electric meters. Walter Lacy Allcroft, 166, Fleet-street, London.

JUNE 8.

11730. An improved fitting for incandescent lights specially applicable for electric incandescent lights. Clarence Metcalfe Stead, 30, Park-row, Leeds.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on June 29.

1900.

8439. Intercommunication by means of electromechanical typewriting or printing instruments. Richardson and Elliott.

10638. Devices for starting electric motors. Thompson. (Fraser Electric Elevator Company.)

10763. Manufacture of filaments for electric incandescence lamps. Thomas.

12296 Fan or air propeller, driven electrically or by mechanical power. Russell.

12392. Clamps for holding the ends of electrical fuses, or links acting as electrical conductors. Callender's Cable and Construction Company, Limited, and Ward.

12598. Driving axles for electric and other vehicles. Contal. (Date applied for under International Convention, Jan. 6, 1900.)

12874. Telephonic apparatus. Blanck.

13085. Method of and means for sounding alarums on electric tram and motorcars. Parietti and Durante.

13362. Starting switches and automatic controllers of electromotors. Moy and Bastie.

13360. Controllers for electric motors. Perkins. (Date applied for under International Convention, Jan. 13, 1900.)

14895. Electric ignition plugs for internal-combustion engines. Simms.

19900. Electric punka-motors. Spühl.

20214 Electric lighting cane or walking stick. Bergmann.

21364 Electric meters. Lux.

1901.

3972. Machines or mechanism employed in the manufacture of pipes or tubes or for covering telegraph and telephone cables and wires with lead or other metallic substance for electric purposes. Claremont and Stratton.

7959. Increasing the economical efficiency of electric incandescent lamps. Bushe.

8803. Safety devices for electrical measuring instruments. Arcioni.

8920. Electric switches. Spagnoletti.

8965 Skates or contact makers carried by cars for use in a surface-contact system of electric traction. Parker.

8967. Method of forming armature coils for dynamos and electric motors, and apparatus for use therein. Parker.

9056. Electric insulation of cotton-covered cables or wires. Claremont and Beaver.

9211. Insulation of electrical conductors and the like and to compounds therefor. Lake. (Hungerford.)

9217. Electric fuses or cut-outs. Johnson. (D. and W. Fuse Company.)

9295. Means for preventing the oscillation of alternators connected in parallel. Haddan. (Blathy.)

9388. Electric arc lamps. Helios Upton Company and Spencer.

9512. Solenoid and other electric coils. Heany.

NOTES.

Book Received.—"The Induction Motor: being a Short Treatise on its Theory and Design," with numerous experimental data and diagrams, by Mr. B. A. Behrend, has just been published by the *Electrical World and Engineer* of New York.

Induction Telegraphy.—It is rumoured that a private company, with a capital of £50,000, has been formed to work the patents which have been granted to Prof. Oliver Lodge relating to induction telegraphy. It may be remembered by our readers that a paper on the subject was read before the Institution some 12 or 15 months ago.

Central Technical College.—The fourth annual dinner of the Association of Old Students of the Central Technical College will be held at the Restaurant Frascati, Oxford-street, on Wednesday, July 3, at 7.30 p.m. Prof. O. Henrici, F.R.S., president of the association, will take the chair. Tickets can be obtained on application to the hon. secretary, Mr. Maurice Solomon, 12, Edith-road, West Kensington, W.

The Franklin Institute.—The *Journal* of the Franklin Institute for June continues Mr. C. J. Reed's paper on "Electrochemical Action," which will be concluded in a later issue. We also notice the continuance of a paper by Mr. George W. Colles on "Rotary Transformers," and a paper on "The Flow of Metal" by Mr. Henry V. Loss. Other interesting papers also appear in this number of the *Journal*.

Wireless Telegraphy on the Irish Coast.—We note that in addition to the Dover station referred to in these columns last week, the Admiralty have commenced the erection of a wireless telegraphy station at Roches Point. When completed this station will probably be the most important on the Irish coast, and it is thought will offer great facilities for communication during the forthcoming naval manœuvres. The next place at which we may expect to hear of the installation of a Government wireless telegraphy station will probably be Queenstown.

The Symons Memorial.—A meeting of the subscribers to the Symons memorial fund was held on the 11th inst. in the rooms of the Royal Meteorological Society, when the executive committee reported that the proposal that the memorial to the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and founder of the British Rainfall Organisation, should take the form of a gold medal, had been approved, and that the sum of £713. 14s. 7d. had been subscribed for that purpose. It was resolved that the medal should be awarded biennially for distinguished work done in connection with meteorological science irrespective of sex or nationality.

New Book.—We have received a copy of a new work entitled "Les Automobiles Electriques," by Messrs. Gaston Lenciel and A. Delasalle, with a preface by Mr. Chas. Jeantaud. This is an octavo volume of 400 pages, published by Mr. Chas. Dunod, 49, Quai des Grands-Augustins, Paris. The book, which contains about 200 photographs and designs, has since publication obtained the silver medal of the Automobile Club of France, and is a complete and concisely-written treatise on the latest developments of electric and petrolio-electric motorcars. It deals not only with the construction, but also with the scientific details of the various inventions used, giving a number of formulæ which may be useful to makers of accumulators.

American Electric Lighting Convention.—From the various accounts which have appeared in the New York technical Press it would appear that the twenty-fourth convention of the National Electric Light Association of America, which has just drawn to a close at Niagara Falls, has proved most satisfactory in every respect. The attendance, we note, was unusually good, and the papers read were almost without exception of a particularly interesting and valuable character, eliciting in most cases useful discussions. At the close of the convention Mr. James B. Cahoon, the newly-elected president of the association, made some remarks on the importance and value of such an association to the electric lighting profession in general.

Wireless Telegraphy on the "Lucania."—A number of Press representatives and others accepted the invitation of the Cunard Steamship Company on Saturday last to witness the Marconi system of wireless telegraphy in operation on the company's fine steamer "Lucania" as she steamed from Liverpool to Queenstown. Communication was kept up with three different stations in succession—viz., the training ship "Conway" off Birkenhead, Holyhead, and Rosslare, on the Irish coast. During the passage to Queenstown large numbers of Press and private telegrams were dispatched to various parts of the country *vid* Holyhead, and communication was shortly afterwards established with Rosslare and maintained until the "Lucania" was within a short distance of Queenstown.

Niagara Falls Power.—We gather from a note in an American contemporary that the Niagara Falls Hydraulic and Manufacturing Company have been compelled to discontinue the use of six dynamos of their installation, owing to the fact that the great flow of water at the outlet of the tail-race into the river is wearing away the rocks. This had become a serious matter on account of the power-house being situate in the immediate vicinity. The device which has been adopted to overcome future destruction consists of a number of pieces of boiler iron riveted together to form the bottom of the tail-race. There are upright side extensions, also of iron, to preserve the side walls. At the end toward the river there is a slight upward curve in the iron plate to throw the water upward, and thus prevent further undermining.

Society of Arts Conversazione.—The Society of Arts conversazione will be held, by arrangement with the council of the Royal Botanic Society, in the gardens of that society, Inner Circle, Regent's Park, on Friday, June 28, from 9 p.m. to 12 o'clock. The Royal Botanic Society's exhibition of rhododendrons will be on view, and it is possible that arrangements will be made for a supplementary exhibition of flowers. A pastoral play, for the benefit of the Soldiers' and Sailors' Families' Association, will be given in an adjacent portion of the gardens. A selection of music will be performed by the string band of the Royal Artillery in the conservatory, and by the band of the Grenadier Guards in the gardens, which will be illuminated. A vocal and instrumental concert by the Royal Criterion Handbell Ringers and Glee Singers, under the direction of Mr. H. Tipper, will be given at intervals in the clubhouse.

Motorcar Restrictions.—It is refreshing to note that even on the question of further restrictions on motorcars as to speed, etc., the county councils are not all of one mind. As one exception to the general opinion that the speed of all motorcars should be reduced to a maximum of 10 miles an hour, we may mention the Worcestershire County Council. On the recommendation of their Highways Committee, the Council have replied in the following strain to the circular letter sent out by the County Councils Association—viz.: "That the Light Locomotives on Highways Act of 1896 should be amended so as not to prescribe the speed at which motorcars should travel, that the ordinary provisions of the law as to furious driving

Digitized by Google

should be applicable, but that some adequate means for identification of motorcars should be prescribed, and that the cars should not be allowed to be driven except by persons certified to be competent drivers."

A Portable Surgical Motor.—A new form of portable surgical motor, which appears to have some good features about it, is described in the current number of the *Lancet*. The 16-volt accumulator is of the sealed type, having a capacity of 18 ampere-hours, and it weighs 34lb. The motor itself is of the type known as the "D" pattern, on account of the shape of the field magnet. The armature is a Gramme ring, and is attached directly to the shaft which carries the cable, thus taking the part of a flywheel. It weighs about 15lb., and is mounted on a gunmetal turn-table, which enables it to rotate and follow the movements of the operator. The entire apparatus with cases included weighs about 70lb. For hospital work the motor is wound to suit the voltage of the main current. The various details of the invention have been perfected by Messrs. Mayer and Meltzer, of Great Portland-street, and the device is said to be giving every satisfaction.

Municipal and County Engineers.—The annual meeting of the Incorporated Association of Municipal and County Engineers, to be held at Leicester on Thursday, Friday, and Saturday next week, promises to have considerable interest for electrical engineers, in that the programme includes the reading and possible discussion of one or two papers relating to electric traction. Among these are: "Permanent-Way Construction for Electric Traction," by Mr. W. Howard Smith; "Methods of Safety for the Overhead Electric Trolley System," by Mr. E. Manville; and "Points as to Wear on Roads caused respectively by Horse Haulage and Motor Traffic," by Mr. W. Worby Beaumont. On Friday also the day's proceedings include a visit to the extensive Falcon Works of the Brush Electrical Engineering Company. The Automobile Club, too, has placed at the disposal of the members a number of motorcars, and on Saturday special trips to the different works of interest in progress in the locality have been arranged for.

Standard Sections.—A committee has recently been appointed by the Institution of Civil Engineers, with the support of the Institutions of Mechanical Engineers and Naval Architects, and of the Iron and Steel Institute, to consider the advisability of standardising the various kinds of iron and steel sections, and, if found advisable, then to consider and report as to the steps which should be taken to carry such standardisation into practice. The committee is composed as follows: Mr. James Mansergh, Pres. Inst. C.E., Sir Benjamin Baker, K.C.M.G., Sir John Wolfe Barry, K.C.B., Sir Frederick Bramwell, Bart., Sir Douglas Fox, Mr. G. Ainsworth, Mr. William Deane, Mr. A. Denny, Mr. J. Allen McDonald, Mr. E. Windsor Richards, Mr. James Riley, Prof. W. C. Unwin, F.R.S., and Dr. J. H. T. Tudsbery (hon. secretary). Mr. Leslie S. Robertson, M.I.C.E., of 28, Victoria-street, S.W., has been appointed secretary to this committee, which has already commenced its work by taking evidence tendered by engineers, manufacturers, and contractors bearing upon the subject of the enquiry.

Telephone Wires in Liverpool.—During the past 12 weeks, since the accident at Liverpool, when a network of telephone and trolley wires fell to the ground in Pembroke-place in a heavy snowstorm, causing the death of two persons, great strides have been made with the work of placing the telephone wires underground. At the time of the accident the National Telephone Company had already begun placing their wires underground, but their engineers have since so pushed forward the work that in the past 12 weeks they have dealt with 6,500 places where telephone wires crossed trolley wires. Where they have not placed the telephone wires underground they have formed them into overhead protected cables, suspended on strong steel wires, and even if through some unforeseen cause a cable should break its indiarubber covering would prevent contact with the trolley wire. The substitution of these cables for the old system made necessary the erection of 71 new poles. The work of placing the lines underground on the metallic return system will be continued until completed, but meanwhile the public are protected. Where the Post Office overhead wires cross the electric main lines the Corporation have put up guard wires, using wooden guards where trolley wires are crossed by telephone lines.

Kew Observatory.—On the occasion of the annual official visitation to the Royal Observatory, Greenwich, by the Board of Visitors, several members of the Royal Society and other scientific bodies were allowed the opportunity of going over the observatory and inspecting the various apparatus which are in use there. The report of the Astronomer Royal has a special interest this year, in that it touches upon the difficulties which arose with regard to the introduction of electric tramways into the locality. Discussing the magnetic observations, the report expresses hope that the example of the London County Council, in proposing to thoroughly insulate the electric tramway system in the neighbourhood of the observatory, will be followed by the South-Eastern Metropolitan Tramways Company. The two systems mentioned would most seriously threaten the magnetic work unless complete precautions are taken, and the report recommends that the Board of Trade should issue regulations on this point, as the magnetic work, which has been carried on at Greenwich for a period of 60 years, "can not be transferred to another site." In the course of the afternoon the visitors were shown the working of the various apparatus, including the elaborate time-recording device, which by means of periodical electric currents regulates the recording time all over the world.

An Electrically-Operated Mine.—There is increasing evidence that electricity as a motive power is being universally employed wherever the circumstances of the work in hand permit. This, perhaps, is more apparent in the States than in any other country, and the rapid development of water power in America is attracting considerable attention just now. One of the most interesting electric power plants which has come to our notice recently is that which is now operating the mines and mills of a large silver company at the Swan Falls, on the banks of the Snake River, in Idaho. The main part of this river runs between such high cliffs that the water cannot be diverted, but at Swan Falls there is a reef of rock lying across the stream and making a fall of 5ft. It was at this point (according to our contemporary the *Electrical Review* of New York) that a dam for the power plant was constructed and four 72in. turbines installed. Each wheel runs under a 17ft. head, generating 750 h.p. Pits for two more wheels have been constructed, and 16 may be added by digging new pits, for which there is room. The cost of the plant, with its entire equipment, and the appliances at the mines and mills, has been about £70,000. Originally power was costing the mining company about £10,000 a year, and this expense was annually increasing, so that when it was found possible to generate electric power the present plan was determined upon, and has only recently been inaugurated.

A Telephone Call-Recording Device. — The British Consul at Philadelphia in a dispatch home describes a new telephone call meter recently patented in

Digitized by Google

America, by which a register can be kept of all telephone calls made both by the subscriber and the telephone company. In shape the new meter has the appearance of a box with a push-rod on the top, while on one side is an indicator which shows the number of calls made. When the subscriber wishes to make a connection, he must press the push-rod before the central office will connect him with the desired number, and the call is thus registered. A comparatively simple counting machine with a dial is provided in the central office, and by means of a switch the attendant can put this machine instantly in connection with the meter. When a reading is to be taken, the switch is turned on and the subscriber is asked to press the plunger on his meter. This releases the spring in the meter, which unwinds, and by a mechanical device it closes and breaks the electrical circuit for each call that has been made. Every time the circuit is closed the central office register counts one. It will be readily seen that such a device has many advantages. Each call being registered, subscriber and company always know how they stand, and it is not necessary to use an attendant's time in recording by hand the number of calls made by the subscriber. Another point which will probably recommend itself is that while the company are strictly informed of all the subscriber's calls, the subscriber himself can keep a check on the company.

The Post Office Telephones.—Some interesting information relating to the new postal telephone system was elicited from the Secretary to the Treasury, as representing the Postmaster-General, in the House of Commons on Tuesday. In reply to Sir James Woodhouse, Mr. Austen Chamberlain said the expenditure already authorised by the Treasury under the provision of the Telegraph Act, 1899, for works in progress or about to be undertaken, amounts to £813,040. Of this amount £677,945 is for the London exchange system and £135,095 for the development of the other parts of the Post Office telephone system in various places, but more particularly in the north-east of England and in South Wales. The actual payments for new works brought to account up to March 31 last amount to £269,941. Mr. Chamberlain went on to say that it is not possible at this stage to state definitely what the final cost of the London exchange system will be, but the whole sum of £2,000,000 authorised by Parliament will be expended in such extensions of the Post Office telephone system as seem most urgently necessary, whether in London or elsewhere. The delay in opening the most important exchanges of the London system has been due to the scarcity of skilled labour, the difficulty of getting materials for contractors, the necessary restrictions on the opening of streets to avoid excessive interference with traffic, and the difficulty of constructing exchanges in buildings in use for other Post Office work. Full particulars of the rates and conditions of the service will be brought before the public at an early date, and it is hoped that it will be available in some parts of London in the autumn.

The Institution Conversazione.—Notwithstanding that some 1,200 ladies and gentlemen attended the annual conversazione of the Institution of Electrical Engineers at the Natural History Museum last Friday evening, it could in no sense of the word be truly described as a "crush." The magnificent hall, tastefully decorated as it was with flowers and palms, presented a brilliant spectacle, and, so far as we could gather, the occasion must have proved at least as successful as any of its predecessors. The guests were received by the President (Mr. W. E. Langdon) and Miss Langdon, and among those present we noticed Sir G. Molesworth, Sir Douglas Fox, Sir H. C. Fischer, Sir A. R. Binnie, Sir Wm. Crookes, Sir Henry Mance, General Webber, Mr. J. W. Swan, Prof. Silvanus Thompson, Mr. A. Siemens, Prof. Ayrton, Prof. Armstrong, and others. A special interest attached to the function in that it marked the thirtieth year of the existence of the Institution. A particular centre of attraction during the evening was the illuminated address recently presented to the Institution by the American Institute of Electrical Engineers, conveying their "sincere thanks for the many courtesies extended to them" during their visit to London and Paris in connection with the International Electrical Congress of last year. The evening on the whole was spent very enjoyably, despite the entire absence of anything in the nature of a "side show." Nor were there the interesting exhibits and demonstrations of the uses of scientific apparatus which one usually associates with this class of function. The nearest approach to anything of the sort was a section of a gigantic Californian tree which looked remarkably like a huge armature in position. Plenty of music, however, was provided by the band of the Royal Engineers, which rendered an excellent selection during the evening under the direction of Lieutenant J. Zommer.

Rontgen Rays and Electric Light Treatment.—The correspondence columns of the various daily papers have been used to a considerable extent of late in discussing the respective merits or demerits of the Röntgen rays for the treatment for lupus, rodent ulcer, etc., and of the electric light treatment. We notice in the *Times*, for instance, a letter from the surgeon to the Röntgen-ray department of the London Skin Hospital on the subject, in which he states that the action in both cases is very similar, but that the Röntgen rays possess every advantage of the electric light treatment with none of its advantages. The points which are put forward by the writer in support of this statement are five in number. In the first place, he says, the Röntgen-ray apparatus costs only about £100, compared with many times that cost for the electric light apparatus. Then there is absolutely no pain or discomfort in the application, whereas the electric light treatment is by no means free from some discomfort and pain. The time required for each application, too, varies from five to fifteen minutes, compared with from one to two hours required in the light treatment. Again, the number of applications need to effect a cure in any given case is much fewer than that of the light treatment. And, lastly, there is no need for any special nurse, and the surgeon can carry out the application single-handed; whereas the same is not possible in the case of the light treatment. In answer to this, Mr. Sydney Holland, chairman of the London Hospital, writes to the *Times* in favour of the Finsen light, which, he states, has been found from actual experience to be far superior to the Röntgen rays, and at the London Hospital they have given up using the Röntgen rays in the majority of cases. When the disease affects the interior of the nose and mouth then the Röntgen rays must be used, as the Finsen method cannot be applied. So far, continues the writer, there is no evidence that the Röntgen rays are germicide, whereas the rays used in the Finsen treatment are powerfully so. Lupus being a bacterial disease, theory would therefore suggest that it would more likely be successful than the Röntgen rays, and this has been found so in practice. The only disadvantage, of the Finsen treatment, in addition to the expense, is the length of the sitting—an hour at a time. The treatment of lupus by the Finsen light is to be discussed at the meeting of the British Medical Association at Cheltenham in August next.

Liquid Hydrogen. — Prof. Dewar delivered the Bakerian lecture of the Royal Society at Burlington House

Digitized by Google

last week, taking for his subject "Nadir of Temperature and Allied Problems." Dealing first with the physical properties of liquid and solid hydrogen, he showed that hydrogen, like oxygen and nitrogen in the liquid condition, had a refractivity in accordance with theory. Coming next to the separation of free hydrogen and other gases from atmospheric air, he described two methods. The one depended on the use of liquid hydrogen to boil the dissolved gases out of air kept at a temperature near the melting point of nitrogen, the other one a simple arrangement for keeping the more volatile gases from getting into solution after separation by partial exhaustion. By the latter method something like $\frac{1}{34000}$th of the volume of the air liquefied appeared as uncondensed gas. The crude gas thus separated gave on analysis: hydrogen, 32·5 per cent.; nitrogen, 8 per cent.; helium, neon, etc., 60 per cent. After removal of the hydrogen and nitrogen the neon could be solidified by cooling in liquid hydrogen and the more volatile portions separated. There existed in air a gaseous material that might be separated with liquefaction of the air. For this purpose air was sucked through a spiral containing glass wool and immersed in liquid air. After the process had been continued for some time the spiral was exhausted at the low temperature of the liquid-air bath and then allowed to heat up. The condensed gas, after purification by spectroscopic fractionation, showed the chief lines of xenon when examined in a vacuum tube. Prof. Dewar then went on to discuss the results given by 15 electrical resistance thermometers for temperatures near the boiling point of hydrogen, pointing out that the law correlating electrical resistance and temperature is not truly known as yet. The hope of being able to liquefy helium, which appeared to have a boiling point of 5deg. absolute, was dependent on subjecting it to the same process as succeeded with hydrogen—only instead of using liquid air under exhaustion as the primary cooling agent, liquid hydrogen under exhaustion must be employed, and the resulting liquid collected in vacuum vessels surrounded with liquid hydrogen. Prof. Dewar concluded by showing how a crystal of nitrate of uranium when placed in liquid hydrogen became for a time self-luminous, on account of the high electric stimulation brought about by the cooling causing actual electric discharges between the crystal molecules. When the cooled crystal was removed from the liquid, the luminosity and electric discharges took place again during the return to normal temperature.

Gloves for High-Tension Work.—The necessity for a good glove for use by electricians at work on machinery or electric wires of high tension will be readily admitted on all sides. With a view to stimulating manufacturers to devise an efficient protection for the hands and forearms which will resist electrical tension and accidental perforation, etc., the Association des Industrielles, of France, some time ago offered a prize for the best glove having these qualifications. In addition to these conditions, of course, it was provided that the glove must be light to carry, and give the worker freedom to use his fingers. The competition was an international one. The committee appointed for the purpose selected six gloves for practical trial, and these were submitted to the Central Laboratory of Electricity at Paris and subjected to two distinct tests. In the first, each glove was placed in a vessel containing mercury, and the glove itself filled with the same metal. The electrical resistance between the mercury inside and outside the glove was measured, the height of the immersed glove being about 20cm., and the power used about 105 volts. In the second series, the gloves were filled with fine sand and placed in a vessel also containing sand, the sand being made conductive with water containing chlorhydrate ammonia. The gloves were allowed to remain wet for 36 hours before the tests were made. The best result obtained was from the glove submitted by Mr. Franz Clouth, of Cologne. In the first case the electrical resistance of the glove was 52,500 megohms, and under the second test 157 megohms. The prize of £40 was eventually awarded in respect of this glove, which is of rubber with a fairly long cuff lined with tricot. The glove is made very strong, and the seams are well overlapped in a slanting direction, so as to prevent destruction. It is coated with a strong layer of rubber without seam or junction. The second best result was obtained with the glove made by Mr. Charles N. Hill, of London. This glove is also made of rubber, with a double lining of tricot. The fingers are reinforced at their junction, and the seams are strengthened on the outside with indiarubber. Under the first test this glove showed a resistance of 6,200 megohms, while under the second series the resistance measured was 24 megohms. A subsequent breakdown test showed Mr. Franz Clouth's glove again to give the best result, standing 11,000 volts for about three minutes, and 12,200 volts for one minute, before it was penetrated. Mr. C. N. Hill's glove stood 1,000 volts for about three minutes, when the glove was penetrated. The gloves were afterwards tested as regards their resistance to wear and tear, and equally satisfactory results were obtained, particularly in respect of the two makes mentioned.

Electric Lamps in Coal Mines.—In view of the present comparatively limited use of electric lamps in coal mines, a paper by Mr. W. O. Wood, read recently before the North of England Institute of Mining and Mechanical Engineers, is of particular interest in that it is devoted to a description of the electric lamps, dynamos, etc., employed at the Murton Collieries. The first installation was made in September, 1897, when a small number of Sussmann lamps were introduced into the colliery. The result was so satisfactory that 500 of these lamps were put into regular work the next month, 100 were added in April, 1898, and 400 in September and October, making 1,000 lamps now in daily and successful operation. At first objection was taken by the miners to the weight of the lamp—about 4lb.—but the difficulties afterwards encountered were more of a practical character, particularly the extinction of the incandescent lamp or bulb and failure of connections and of batteries, the last being the most troublesome. The number of failures of the ordinary oil safety lamps previously in use at this colliery was 2·11 per cent., and even at the first the failures of the electric lamps were not very excessive, being from all causes only 3 per cent. At the present time, however, as the result of various improvements, the failures are only 0·01 per cent. Before adopting the lamp the author made many experiments to satisfy himself that ignition would not take place if the bulb were broken in an explosive mixture. This was done in mixtures of coal gas and mine gas with incandescent lamps varying from 1 c.p. to 16 c.p. and currents varying from 4 to 110 volts. The result was invariably the same, and out of many experiments there was no ignition, while faulty oil safety lamps, under the same circumstances, at once exploded the inflammable mixture. The lamp is made in two patterns: No. 1 with an ordinary or fixed bulb, and No. 2 with a top (patented by the author) containing a removable bulb, so that in the event of a bulb failing in the mine, the deputy or other official can replace it by a new one in a couple of minutes. The secondary battery is of the Faure or pasted type. The complete battery weighs 3½lb., and has an E.M.F. of two volts per cell, with a capacity of 8½

Digitized by Google

ampere-hours, which maintain the incandescent bulb alight for eight to ten hours with one charge. The battery can be charged up to 0·8 ampere, but this point should never be exceeded. Each battery has a capacity of 5½ ampere-hours, so that taking the charging rate to be 0·65 ampere, it is necessary to leave them connected for 13 hours, or for 12 hours at 0·7 ampere, the lower rate being preferable. The total cost of working the lamps over several months, including all charges except interest on capital, and the cost of running the dynamos, was 3·79. With wages at 52 per cent. above the basis rates, this figure was increased to 4·82. The life of the battery up to the present time averages 10 months, but certain improvements have recently been made whereby it is expected to reach 12 months.

Lord Kelvin on James Watt.—At the recent celebrations in connection with the ninth jubilee of Glasgow University, Lord Kelvin gave a most interesting oration on James Watt, whose name, he said, was famous throughout the whole world, in every part of which his great work had conferred benefits on mankind in continually increasing volume up to the present day. Referring to Watt's early career, Lord Kelvin thought it was fitting that the University of Glasgow, in the celebration of its ninth jubilee, should recollect with pride the privilege it happily exercised 145 years ago of lending a helping hand and giving a workshop within its walls to a young man of no university education, struggling to begin earning a livelihood as a mathematical instrument maker, in whom was then discovered something of the genius destined for such great things in the future. It was about the year 1761 or 1762 that Watt tried some experiments on the force of steam in a Papin's digester, and formed a species of steam-engine by fixing upon it a syringe ½in. diameter with a solid piston, and furnished also with a cock to admit the steam from the digester or shut it off at pleasure, as well as to open a communication from the inside of the syringe to the open air, by which the steam contained in the syringe might escape. That single-acting, high-pressure syringe engine, made and experimented on by James Watt 140 years ago in his Glasgow College workshop, now in 1901, with the addition of a surface condenser cooled by air to receive the waste steam and a pump to return the water thence to the boiler, constituted the common road motor, which, in the opinion of many good judges, was the most successful of all the different forms tried within the last few years. Referring now more particularly to Glasgow University itself, Lord Kelvin said it was certainly unique in being the first British university to have an engineering school and professorship of engineering. Again, Glasgow was the first university to have a chemical teaching laboratory for students and also a physical laboratory. Pioneer though it was in these three departments, it had been outstripped within the last 10 or 15 years by other universities and colleges in the elaborate buildings and instruments now needed to work effectively for the increase of knowledge by experimental research and the practical instruction of students. But there was no lagging to-day in the resolution to improve to the utmost in all affairs of practical importance, and they almost saw attainment of the further aspirations to excel over all others in the magnificent James Watt engineering laboratory of the University of Glasgow, to be ready for work before the expected meeting of the Engineering Congress next September. Now, through the magnificently generous kindness of Mr. Andrew Carnegie to the people among whom he has made for himself a summer home in the land of his birth, all the four Scottish universities could look forward to a largely-increased power of benefiting the world by scientific research, and by extending their teaching to young people chosen from every class of society, who were likely to be made better and happier and more useful to our country by university education.

Electricity and Municipal Trading.—In a letter to the *Times* under this heading Mr. Sydney Morse, chairman of the Municipal Trading Committee of the London Chamber of Commerce, condemns the policy taken up by far too many of our local authorities of opposing everything in the nature of private enterprise advanced in this country. It is difficult to understand, he says, why our municipalities and local authorities, to which so much public work of the utmost importance has been entrusted, should place difficulties in the way of the extension of private enterprise and should be allowed to continue to do so. Municipal trading is always put forward as a method of relieving the rates by keeping for the ratepayers the profits made by those whose only object is alleged to be profit-making without regard to the interests of the ratepayer. The cardinal principle underlying all trade is that the trader must give a good article at a reasonable price if he is to find customers and so make a profit. In the some manner with regard to public undertakings, such as the supply of electrical energy, or the service of railways and tramways, unless the business be well managed and the company or trader give what the public requires at a reasonable price, there are no profits. Municipalities and local authorities have entirely neglected these considerations. Indeed, they have denied them. By certain Acts of Parliament the consents of municipalities and local authorities are necessary to the establishment of an enterprise; but municipalities and local authorities in considering whether such consents should be given have taken a line which, he submits, is absolutely opposed to the interests of the ratepayers whom they represent. For example, in connection with electric lighting and tramways, instead of simply requiring that the service shall be good and the price reasonable, they have made conditions increasing capital expenditure—often putting upon the undertaking what are in fact public improvements—and then have insisted upon power to purchase the undertaking after a very short period at a price approaching the price of old iron. Again, when the local authority has been the possessor of an electric lighting station or of a provisional order which they have not put into force, a condition is added that the tramways or railway shall take all electrical energy required from the local authority at a price giving a large profit to the authority. The natural result follows: the service is not so good as it might be, it costs more than it would otherwise cost, and there is nothing to encourage the trader to extend the undertaking, all the result of the action of the local authority, but all put down to the company or trader. If, continues Mr. Morse, science continue to give us new inventions, sooner or later corporations will be driven to scrap plant, the cost of which will still be represented in their books by unpaid loans, and for the repayment of which rates will have to be levied. In matters of ordinary trading the usual economic laws will protect the public sufficiently. And where parliamentary powers are required, and the industry is in the nature of a monopoly, the public interests can be sufficiently safeguarded by providing for an efficient service, fixing maximum rates and maximum profits, and by provisions similar to the auction clauses in Gas Acts for placing additional capital. If, Mr. Morse concludes, the members of our municipal and public bodies really have at heart the interests of the public as distinguished from the public body, they should accept such a solution.

Digitized by Google

ELECTRIC POWER SUPPLY ON TYNESIDE.

The successful inauguration by the Right Hon. Lord Kelvin, G.C.V.O., F.R.S., LL.D., of electric power supply on Tyneside (the proceedings in regard to which ceremony are detailed in another column), marks the official completion of the first of a new series of large power transmission schemes which cannot but have a very beneficial influence on the status of the electrical industry as a whole. The undertaking under notice differs from the Trafford Park power scheme recently described in these columns in that the area of supply which it embraces is relatively much larger, thereby involving problems of distribution not common to the Trafford Park scheme, whence our justification for designating the Tyneside supply the first of a new series. As will be seen later on, the predominating idea in designing the scheme has been to secure absolute immunity from serious breakdowns, and to this end more than usual attention has been given to the transmission lines and distributing network, the system being single-pole throughout, with single-core distributors laid in separate channels for the three-wire low-tension network, by which means liability to short-circuits and their attendant disturbance is effectively excluded. It is, of course, absolutely essential to the lasting success of any scheme designed for the distribution of power in bulk to secure immunity from serious breakdown, and the means adopted to attain this end lend additional interest to any scheme for the supply of electricity in bulk. New problems have had to be solved, and to those who have been engaged in the pioneering work must be accorded full credit for the bold manner in which these have been tackled. Practice in regard to such power schemes is likely to become standardised to a much greater extent than is possible in ordinary central-station work, because the general features and conditions of supply in each case will be practically identical in so far as supply of power in bulk to more or less distant consumers is concerned. Experience may suggest modifications, but, apart from the minor details, we venture to think the most essential advancement will be in adopting larger units of plant; and unless manufacturers at home make provision for the construction of standard sets of, say, 3,000 kw. capacity each, large orders are bound to go abroad. However, we are wandering from the main purpose of this article—namely, to describe the electric power supply on Tyneside.

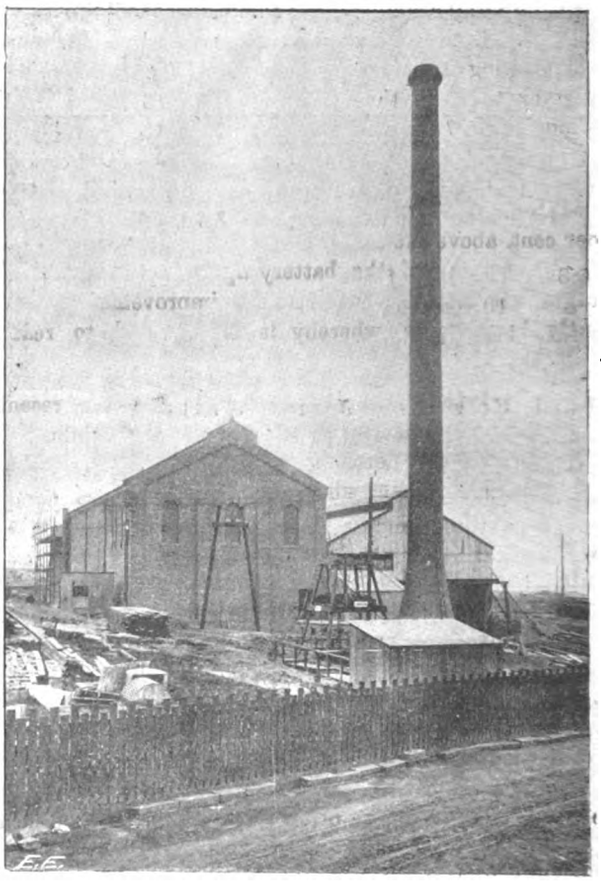

FIG. 1.—Neptune Bank Power Station in course of Erection

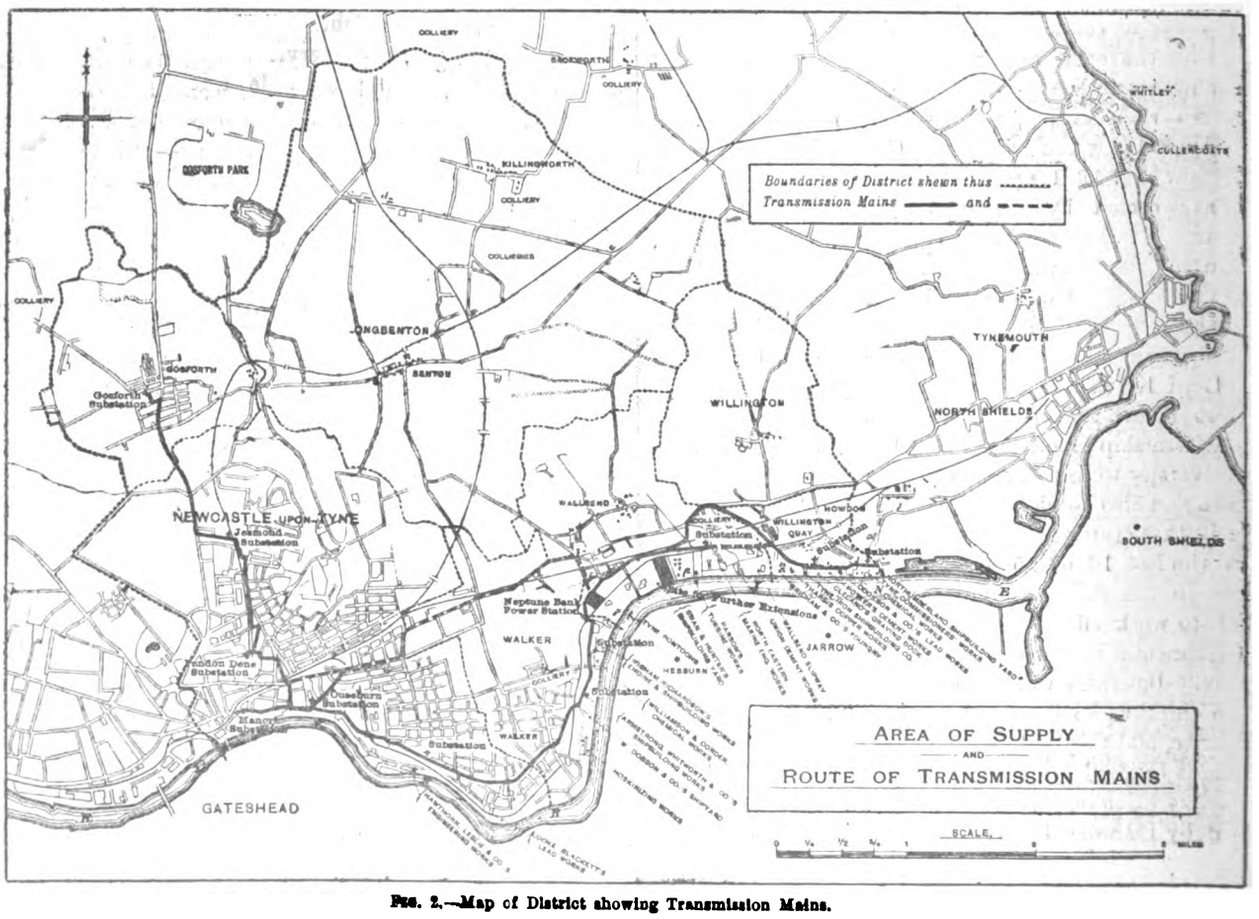

FIG. 2.—Map of District showing Transmission Mains.

The generating station, which is situated at Neptune Bank, is the preliminary power station commenced over a

Digitized by Google

year ago by the Walker and Wallsend Union Gas Company on a somewhat smaller scale, and since taken over by the Newcastle-upon-Tyne Electric Supply Company, a new site outside the then existing area of supply, and at the same time to extend this area. The order was granted in August of last year, whereupon an arrangement was

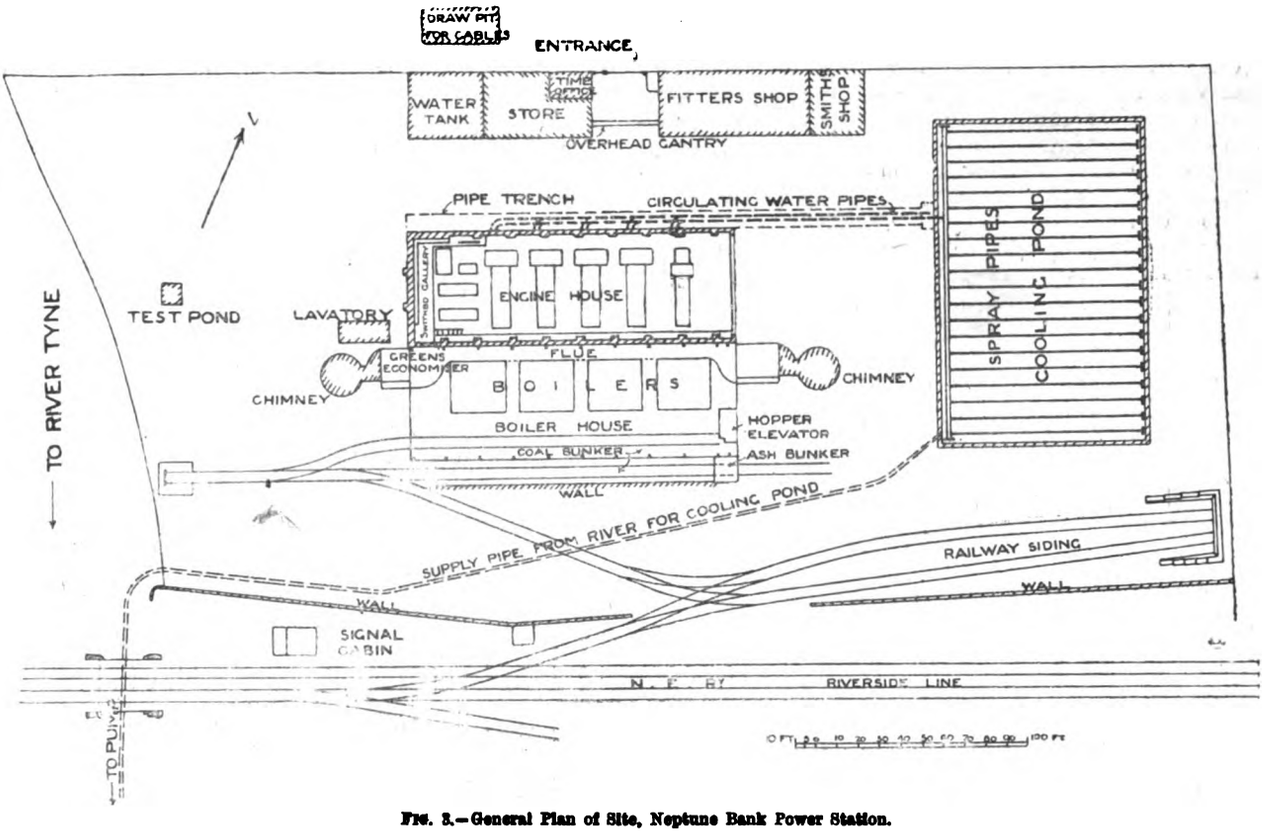

FIG. 3.—General Plan of Site, Neptune Bank Power Station.

Limited. The latter company, it will be remembered, inaugurated an alternating-current supply of electricity from their works situated at Pandon Dene as long since as 1890. This supply was used chiefly for lighting purposes over the company's Newcastle area, but the demand increased to such an extent that last year the Pandon Dene site became obviously too small for the growing requirements, and powers were therefore sought to obtain entered into with the Walker Urban District Council and the Walker and Wallsend Union Gas Company, whereby the Electric Supply Company took over the power station then being erected at Neptune Bank and undertook to supply the requirements of the parties concerned in bulk, in addition to their own needs. Fig. 1 shows the power station in course of erection.

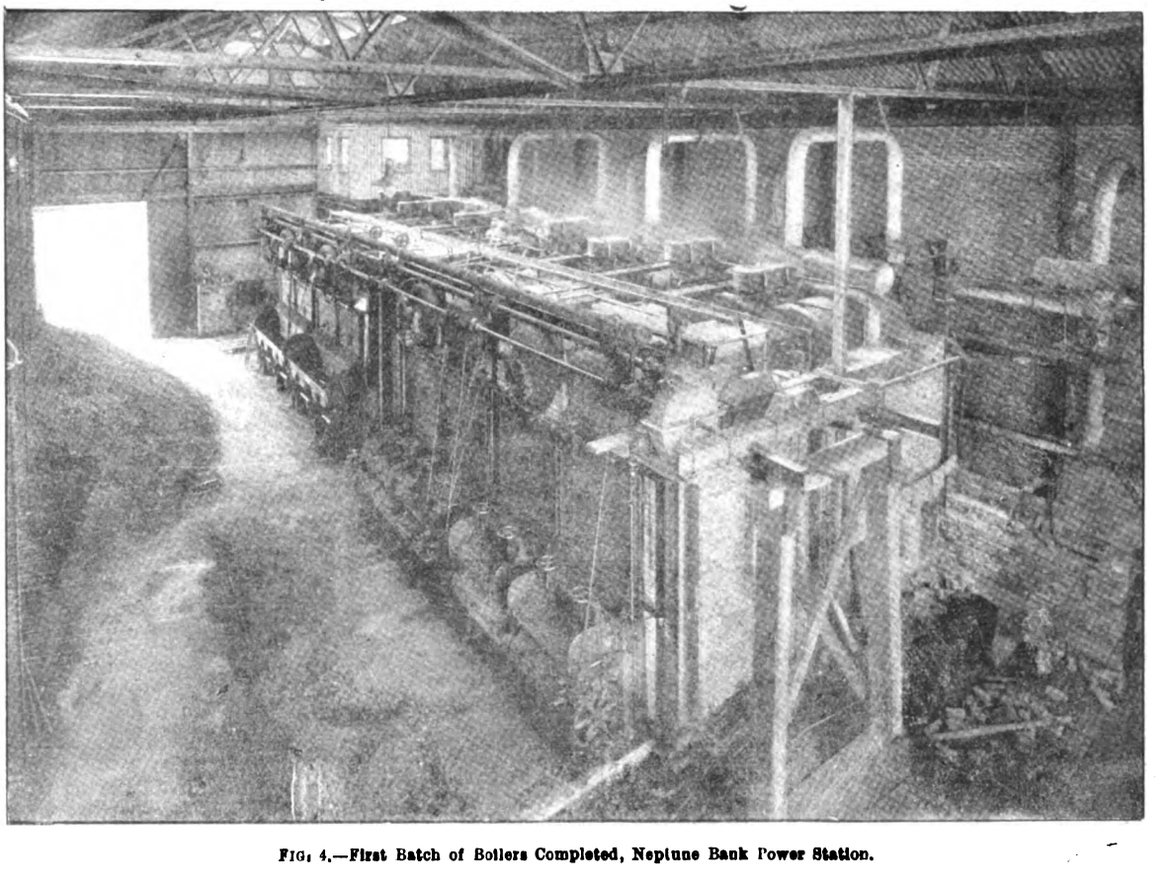

FIG. 4.—First Batch of Boilers Completed, Neptune Bank Power Station.

It should be mentioned that when the gas company

Digitized by Google

obtained their order, Parliament refused to allow them to utilise any site but one which they had purchased for gas purposes at Neptune Bank, Wallsend, which, therefore, had to be adopted in the first instance although not actually on the river. Having regard to the position of the site, the station has been designed for a comparatively moderate plant capacity, and when the plant at present installed, together with that on order, has become loaded it is intended to erect another generating station on the riverside site which has been acquired by the company. This new site, which is shown on the map of the district (Fig. 2), is about 15 acres in extent, and centrally situated relative to the pick of the power supply area.

The gas company, in putting down their station, in the first instance adopted the three-phase system, generating at a pressure of 5,500 volts with a periodicity of 40 ⁓ and transmitting at this pressure, then either stepping down by static transformers to 440 volts or feeding a continuous-current three wire network by means of synchronous motor-generators, the motors being wound to work on the full pressure of 5,500 volts. The periodicity of 40 ⁓ and secondary voltage of 440 were adopted because they conformed to both Continental and American standards, thus enabling all class of apparatus to be obtained at an economical price. When the Newcastle Company took over the station the question of transmission pressure was reconsidered with a view to deciding whether it would be advisable to transmit at a higher voltage, but it was found that with the existing Board of Trade regulation as to thickness of insulation the original pressure of 5,500 was within a small percentage of being the most economical possible voltage for the present requirements of Newcastle. The voltage of the Newcastle transmission line is therefore 5,500, which will be transformed to continuous current at 440 volts pressure by means of synchronous motor-generators located in the various city sub-stations, whence the continuous-current feeders radiate to the three-wire distributing networks. Fortunately there has been no incontinuity in the design of the scheme, Mr. Charles H. Merz, consulting engineer to the Newcastle Company, having been responsible for the scheme since its initiation.

The Neptune Bank site, on which the generating station is erected, is about 350 yards from the river, and 60ft. above its level. It is served by a siding from the North-Eastern Railway Company's riverside branch. The position is shown on the accompanying map of the district (Fig. 2), while the general arrangement of the site is seen in Fig. 3.

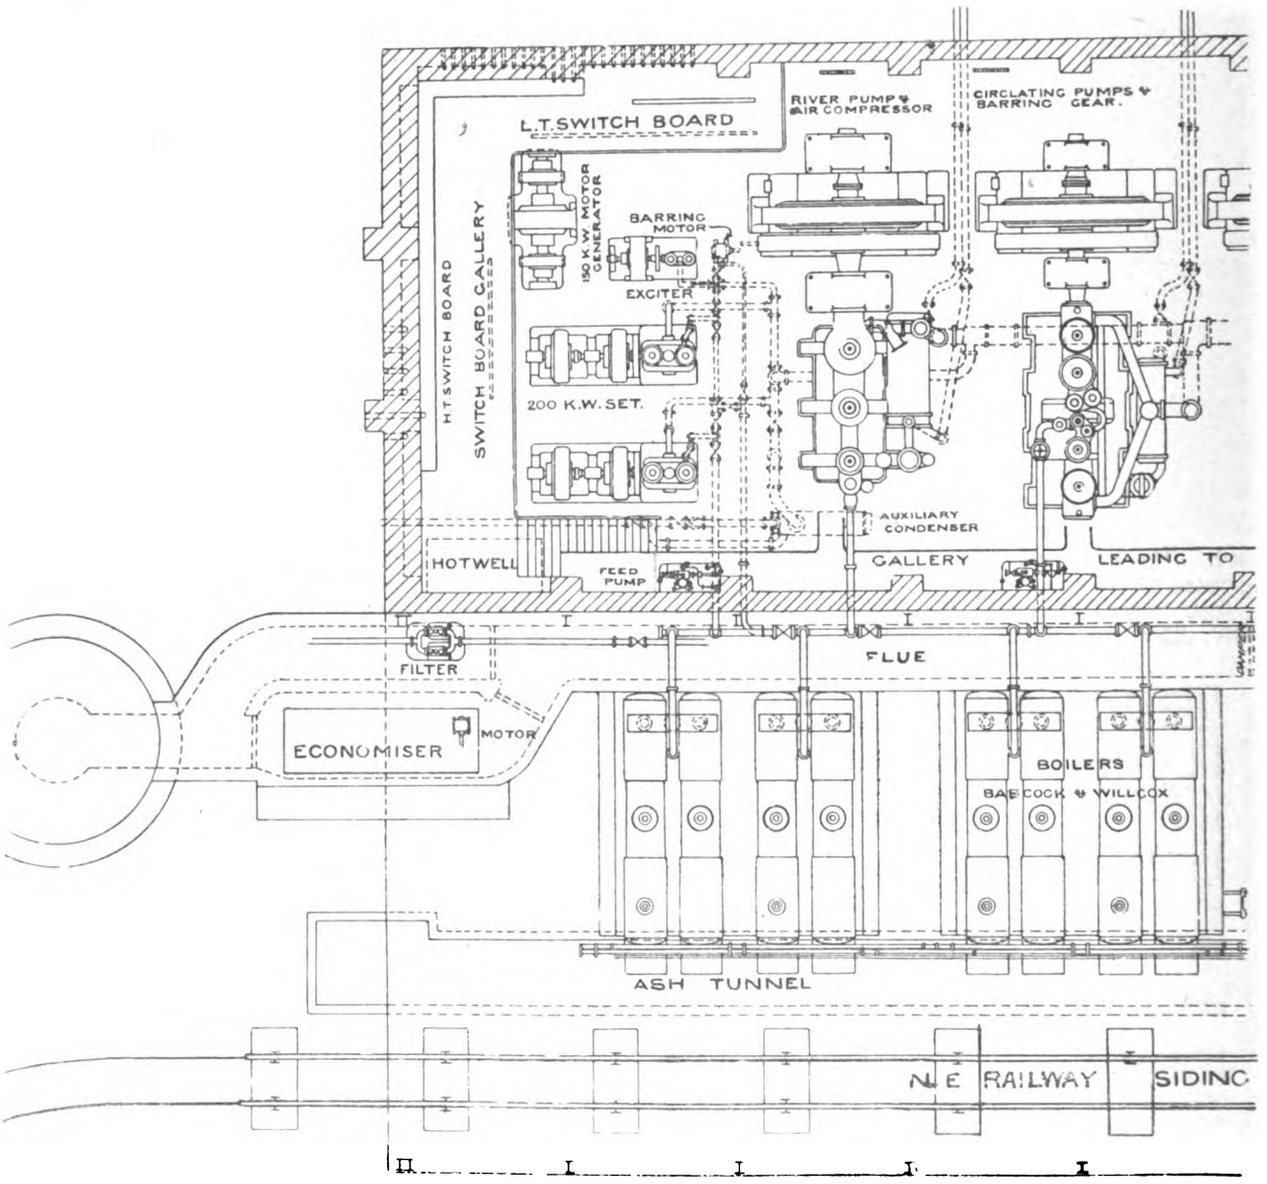

FIG. 5.—Detailed Plan of Neptune Bank Power Station (Left Half).

From the latter figure it is apparent that the station lies to the north and parallel with the railway, and that room has been found on the site for the necessary stores, fitting shops, test pond, etc., as well as for the power station and its cooling pond. One of the first problems in connection with the site which had to be solved was the question as to the best method of providing circulating water for the condensers. In order to settle this point, the capital expenditure, annual cost of running pumps, wayleave rent, etc., were got out for a pumping station at the river bank and a pair of 24in. pipes connecting this with the power station. It was found, however, that it would be cheaper, both in first cost and in running charges, to instal a cooling pond fitted with Korting's spray pipes on the site itself, merely pumping from the river the water necessary to make good the loss through evaporation. A brief description of this cooling pond may not be out

Digitized by Google

of place here. The present plant is for dealing with 120,000 gallons of water per hour. This water is delivered through special centrifugal spray nozzles. There are 90 15mm. nozzles carried on 15 rows of 4in. pipes over a pond 146ft. by 58ft. by 3ft. deep. The main distributing pipe is 14in. diameter, and each line of 4in. pipes carrying nozzles has a valve, so that it can be shut off or turned on independently of the other lines. The distributing pipes are supported on piers provided with cast-iron capping plates. The pressure of water required at the nozzles for dividing the water into spray sufficiently fine for efficient cooling is 7½lb. per square inch, or, say, 15ft. head. The water is carried from the engine-room through a main pipe 14in. diameter, and there is a 14in. main suction pipe taken from the pond to the engine-room. From the suction pipe branches are taken to three centrifugal pumps working in connection with the condensers on the several engines. Each of the pumps is driven independently by a 20-b.h.p. Bruce Peebles motor, and is designed for a duty of 1,000 gallons per minute against a total head, including pipe friction, of 25ft. The pumps deliver into surface condensers, and from these the water is carried back through the main pressure pipe to the cooling pond. Additional pipes and nozzles are now on order for increasing the capacity of the cooling plant from 120,000 to 330,000 gallons per hour.

Coming now to the power station itself, it may be mentioned that this comprises two bays, each 52ft. wide by 160ft. long, one bay forming the engine-room, the other the boiler-house. The engine-room is of brick construction, while the boiler-house is of iron. The basement level of the engine-room is on the same plane as the firing floor of the boiler-house, while the engine-room working level and that of the North-Eastern Railway siding is 8ft. above this. This difference of level, while doing away with the necessity of having an underground flue, allows the feed pipes, etc., to be readily brought through the engine-room basement directly into the boiler-house without coming above the working level of the engine-room, and at the same time shortens somewhat the main steam-pipes. The railway siding is, as already mentioned, some 8ft. above the stoking level, thus allowing a considerable quantity of coal to be stored in the bunkers both inside and outside the boiler-house.

The height of the engine-room from basement to the underside of the roof tie-bars is 40ft. 6in., and a 25-ton "Booth's traveller" serves the whole length of the room. At the west end of the engine-room is located the switchboard gallery, which is elevated some 10ft. above the engine floor level, means of access being provided from the gallery to the middle platforms of all the main engines, as well as to the gratings in the boiler-house, from which the stop-valves to the steam-piping system are controlled. Both the high-tension and low-tension switchboards are also operated from this gallery, besides which is provided a reply gong engine-room telegraph for each engine, one dial being fixed to the gallery rail opposite its machine panel, while the corresponding dial is secured to the wall opposite the engine stop-valve. The engine-room basement is divided longitudinally by concrete walls into two chambers, in one of which all the machine rheostats are placed and all the high and low tension cables carried to

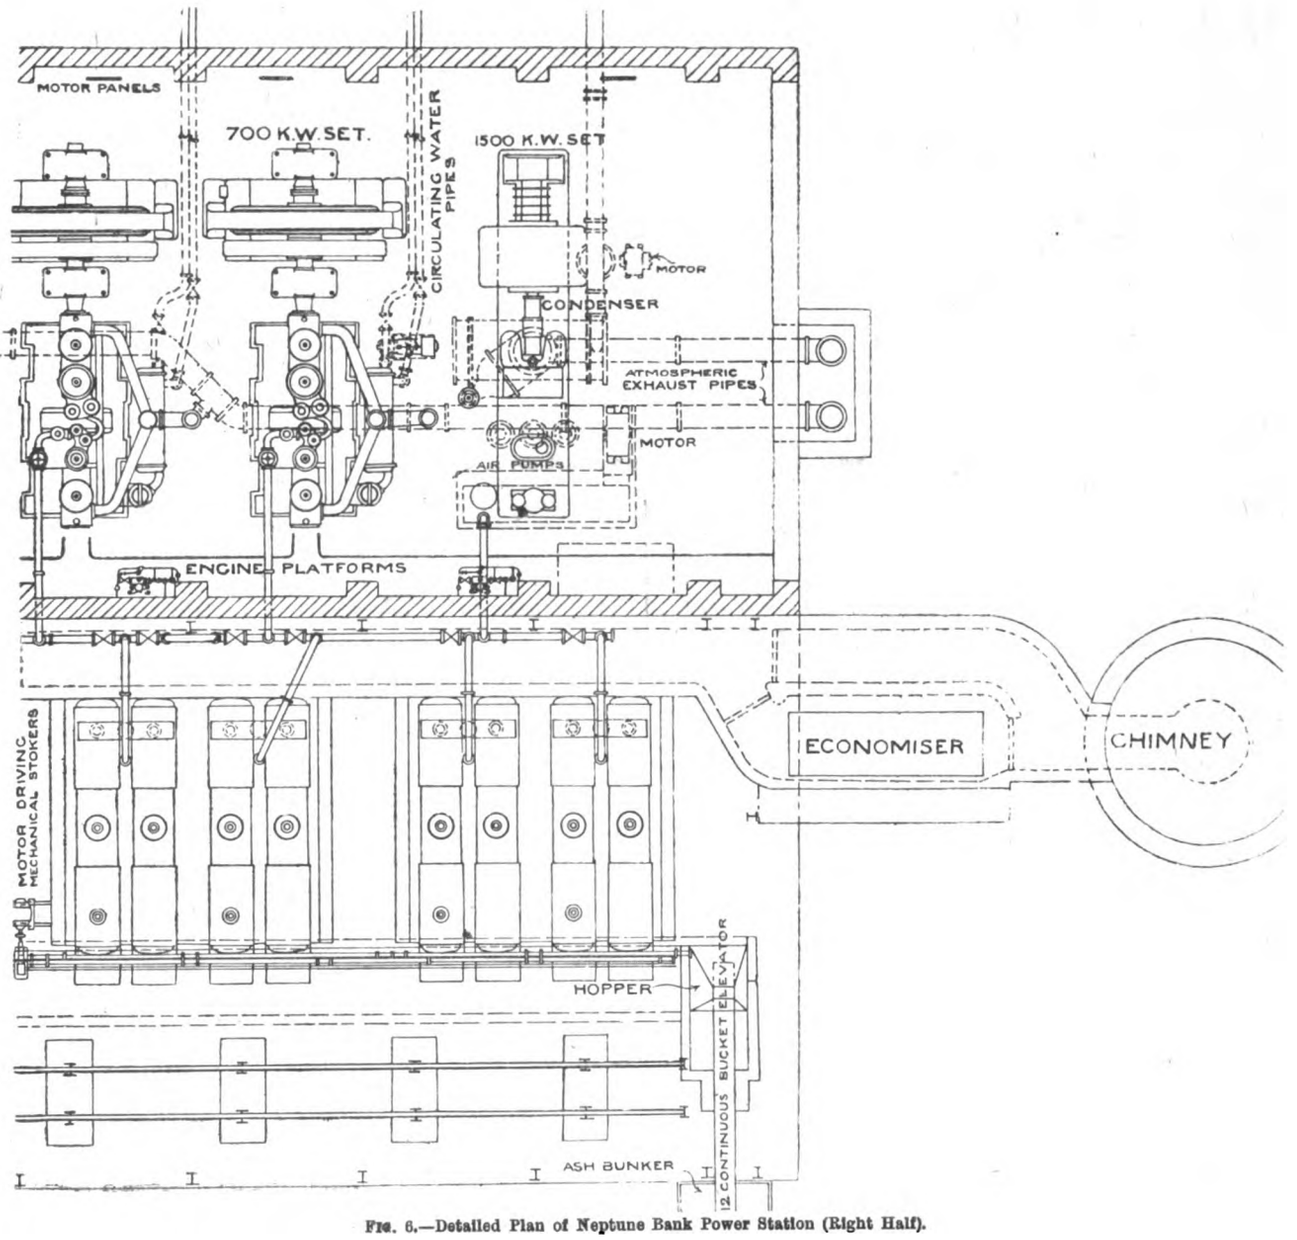

FIG. 6.—Detailed Plan of Neptune Bank Power Station (Right Half).

Digitized by Google

the switchboard. The other chamber is occupied by the various exhaust, feed, circulating, and water-service pipes, the hot-wells, the motor-driven centrifugal pumps, the grease separators, and the Wheeler condenser for the Belliss exciter sets. This is an arrangement much more commonly adopted on the Continent than in this country, and one which has been repeatedly advocated in these columns on account of its obvious advantages. All the high-tension machine cables in the basement are made up of three single separately-insulated rubber cables, held together by a braided covering, so that they can be connected on to the three machine terminals without the interposition of a dividing box, it being only necessary to strip back the braid and to connect the individual cables to their respective terminals on the generator. These high-tension cables are carried up to the switchboard each in a separate wrought-iron pipe. The low-tension machine, exciting, and power cables are all of the plain rubber-covered single-core type run in porcelain rack insulators, the low-tension feeder cables being surrounded by porcelain sleeves, and clamped to the wall up to the point where each cable drops into its own pipe duct, whence it is carried outside to join the solid system. The total absence of woodwork from all parts of the basement is another noticeable feature, and the ironwork is, moreover, earthed to a bare copper solid wire of ·1 square inch sectional area, which runs the whole length of the basement, and is connected both to the engine piping system, the generator bed-plates, and to two special earth-plates outside. The centre of the star winding of each three-phase generator is also earthed, but by means of a separate lighting insulated cable, which is, however, connected eventually to the same earth-plates

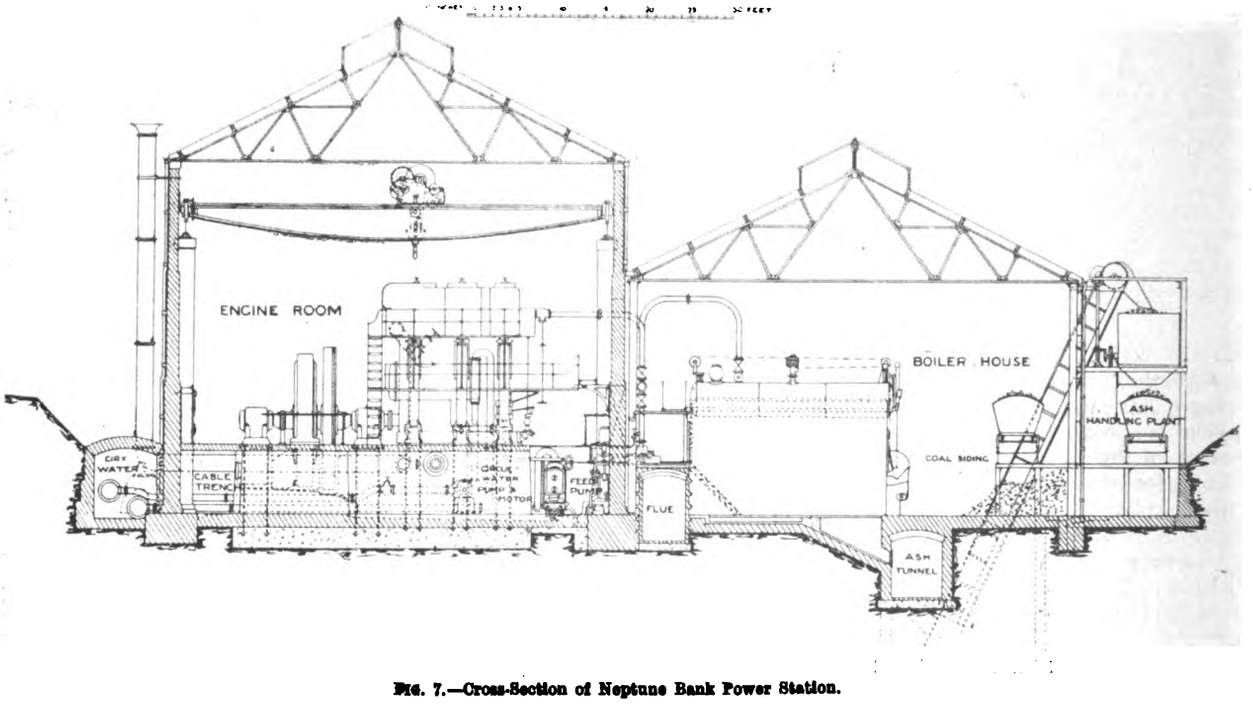

Fig. 7.—Cross-Section of Neptune Bank Power Station.

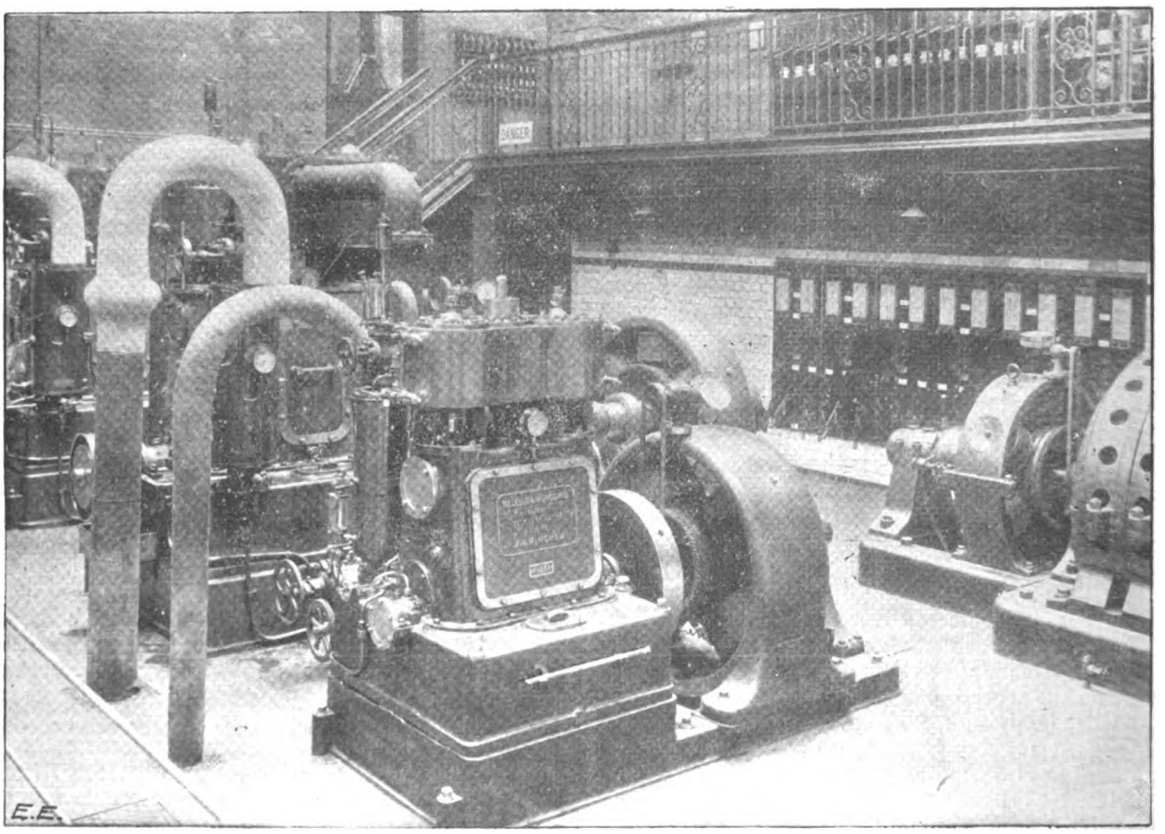

Fig. 8.—View of Belliss-B.T.H. Sets and Direct-Current Machine Panels.

Digitized by Google

which serve the rest of the system. In the cable basement there is also provided a small direct-coupled motor-driven air-compressor, and a complete system of pipes leading to the switchboards and to all the machines, by means of which air at a pressure of 60lb. per square inch is utilised for freeing the armatures and high-tension switch gear from dirt and dust.

When fully installed, the equipment of this power station will be briefly as follows: eight Babcock and Wilcox boilers; two 300-b.h.p. Belliss engines, each driving two 100-kw. 240-volt direct-current generators; one 75-b.h.p. Belliss engine driving 50-kw. 240-volt direct-current generator; four 1,400-i.h.p. triple-expansion engines, each driving one 70-kw. 3,500-volt three-phase alternator; one 1,500-kw. Parsons turbo-alternator, 5,500 volts three-phase; one 1,500-kw. 5,500 to 240 volts, three-phase, continuous-current, synchronous motor-generator.

Boiler-House Equipment.

In the boiler-house (Fig. 4) are installed, or in course of installation, eight Babcock and Wilcox boilers, each having 4,020 square feet of heating surface, and being capable of producing 14,000lb. of steam per hour at a pressure of 200lb. per square inch. These are arranged in batteries of two boilers each. Superheaters are fitted to each boiler of sufficient capacity to impart 100deg. to 120deg. F. of superheat to the whole of the steam. These can, however, be flooded so that saturated steam is also available. Two types of mechanical stokers are employed, one by Messrs. T. and T. Vicars, the other being the chain-grate class by Babcock and Wilcox. These are driven by a shaft running the full length of all the boilers, power being supplied by a Bruce Peebles motor fixed in a central position relative to the shaft. An economiser, by Messrs. Green, is placed in the flue close to the base of the chimney, a by-pass flue being provided so that the gases can pass direct to the chimney if required. The economiser tube scrapers are electrically driven, and work continuously while the economiser is in use. An ash elevator (see Fig. 7), by Messrs. Graham, Morton, and Co., conveys the ashes from the ash tunnel to a bunker, which in turn discharges into a truck on the railway siding. This is also electrically driven. The siding is provided with an electric locomotive for handling coal-trucks, etc.

Piping.—The steam-piping (see Figs. 5 and 6) consists of one main running the full length of the boiler-room at the back of the boilers above the flue. Steam is supplied to this by branches from each boiler, one branch also being taken through the centre wall for the supply of each of the large engines. The Belliss sets are supplied from an auxiliary steam-pipe, which also supplies the feed pumps. Under normal conditions the exhaust steam is passed through surface condensers and returned to the hot-well, the circulating water being forced by means of electrically-driven centrifugal pumps through the condensers, and thence to the cooling pond already described. Atmospheric exhaust pipes are also provided, and a separate automatic atmospheric valve is supplied for each engine. Four feed pumps by Weir and Co. are arranged to feed the boilers, either direct or through the economiser, with water either from the hot-wells or town water-mains. Oil separators are placed in the exhausts from the Belliss engines, and filters are fitted to the air-pump discharge mains. Rankine filters are also installed on the delivery pipe before it reaches the economiser.

Engine-Room Equipment.

Two Belliss engines (Fig. 8), each of 300 b.h.p., drive the direct-current generators, and one of 75 h.p. drives the small exciter. They exhaust through oil separators into a Wheeler surface condenser. The engines driving the 700-kw. sets are all of the triple-expansion, vertical, inverted type, fitted with both expansion and emergency governors. One of these is by the Wallsend Slipway and Engineering Company, and is fitted with Corliss valve gear. This engine is remarkable for the economy which it effects in steam consumption, the variation from quarter-load to full load being between 9·94lb. to 10·42lb. per horse-power hour, or between 16·89lb. to 21·81lb. per kilowatt-hour. The lowest consumption was observed at three-quarter load, the consumption at quarter-load being at the rate of 10lb. per horse-power hour. The results of the water-consumption tests for this engine are tabulated herewith.

Summary of Results.

Description of trial.	Duration of trial.	Average steam pressure.	Average vacuum.	Revolutions per minute.	Average total indicated horse-power.	Total kilowatts per hour.	Water per indicated horse-power per hour.	Consumption per kilowatt per hour.
	Hours	Lbs.	In.				Lbs.	Lbs.
¼ load	1½	200	25	99·3	364	167	10·0	21·8
½ load	1½	200	25	98·7	594	332	10 03	18
¾ load	2	200	25½	99·2	850	503	9·94	16·89
Full load..	2	200	26	100·3	1,177	719	10·42	17·09

The three Wigham-Richardson's engines (Fig. 9) are of the four-crank triple-expansion type, balanced on the Yarrow, Schlich, and Tweedy system, and naturally run without appreciable vibration. Governing is done by a Stumpf flywheel governor mounted direct on the crank-shaft, and on all engines an Aspinall emergency governor cuts the steam off entirely at 15 per cent. above the normal speed, which is 100 revolutions per minute. These engines will drive their generators at full load (700 kw.) when exhausting to atmosphere. The disposition of the several items of plant described is shown in the detailed plan (Figs. 5 and 6) and the cross-section (Fig. 7).

Large Alternators.—The large alternators are of the three-phase type with revolving fields and stationary armatures, and were supplied by the British Thomson-Houston Company, Limited. Each machine is placed tandem to its engine, the field being mounted on an extension of the engine shaft, 24in. in diameter. The armatures are arranged to slide parallel to the shaft on base-plates secured to the foundations by bolts. The normal output of each generator is 700 kw. at 5,500 volts, the speed being 100 revolutions per minute. The fields have 48 poles, thus giving a frequency of 40 cycles per second. The armature core is built up of punchings of the best grade sheet iron specially selected for high permeability and low hysteresis loss. They have been japanned before assembling, and are further insulated from each other by sheets of paper inserted to reduce the eddy-current loss. Slots are punched on the inner side to receive the winding, which is held firmly in place by means of wooden wedges. The punchings are assembled with ventilating spaces at intervals to allow of a free circulation of air in direct contact with the core and winding. The armature winding consists of separately insulated former-wound coils laid in the slots and secured therein by the above-mentioned wooden wedges, the coils being completely insulated before being placed in the armature. The winding is so arranged that in case of a burn-out the defective coil can be readily taken out and another put in its place. There is one slot per pole per phase, and the shape of the pole-pieces is such that the wave shape approximate closely to that of a sine curve. The field poles are built of punchings bolted together, these punchings being of high permeability, thus reducing the energy required for excitation. Also hysteresis and eddy-current loss due to fluctuations in the magnetic flux through the poles caused by the reaction of the armature current are almost entirely eliminated. The poles are firmly secured to a cast-steel ring supported by a cast-iron spider mounted on the shaft. The field winding consists of copper strip wound on edge, the successive turns being carefully insulated from each other and from the core. The normal exciting voltage is 250. Carbon brushes are used for the collector rings. The commercial efficiency of the generators is not less than 95 per cent. at full load and 91½ per cent. at half load, excluding the excitation, and the generators will carry an overload of 25 per cent. for half an hour without injury. The rise in voltage upon throwing off full non-inductive load does not exceed 7½ per cent., and the temperature rise after a 10 hours' run at full load does not exceed 40deg. C. as measured by the thermometer. The appearance of these sets is seen in Fig. 8.

Digitized by Google

Continuous-Current Generators.—Each continuous-current set consists of two 100-kw. generators, supplied by the British Thomson-Houston Company, Limited, connected up tandem-wise to a Bellis engine, the arrangement being such that the armatures are interchangeable. Each generator has an output as a shunt machine of 100 kw. at all voltages from 260 to 270 when running at a speed of 380 revolutions per minute, and as a compound machine gives 250 volts at no load and 262 volts at full load. The armature cores are of the slotted type, with special ventilating ducts to ensure low temperature rise. The armatures are drum wound, the windings consisting of interchangeable copper coils set into slots in the periphery of the core and insulated therefrom with layers of specially prepared paper and linen. The commutators consist of segments of hard-drawn copper insulated from each other by mica strips, and mounted on a cast-iron shell. The brushes are of carbon provided with a flexible copper conductor connecting them to the brush-holders, thus entirely avoiding all sliding contacts between brush and holder. The field magnets are circular in form, with six inwardly projecting poles of mild steel, and are divided into two parts horizontally. The magnet coils are wound on separate formers, so that they can be readily slipped on or off. The bearings are of the self-aligning, self-oiling type, provided with oil rings. After a 24 hours' run at full load the surface temperatures of any part of the armature or field windings does not exceed 45deg. C. above that of the surrounding air.

Motor-Generator in Generating Station.—This motor-generator was supplied by Messrs. Richardsons, Westgarth, and Co., and is designed for a twofold purpose—that is to say, either for receiving alternating three-phase currents and delivering direct current, or *vice versâ*. The set consists of one three-phase synchronous motor wound for the full pressure of 5,000 volts direct coupled to two continuous-current machines, each machine having an output as a shunt machine of 75 kw. when running as a generator at 400 revolutions per minute. Each machine is shunt and compound wound, and gives at full load 260 to 270 volts. The combined commercial efficiency of this set at full load and normal voltage, and running either way, is not less than 85 per cent. The temperature rise after 10 hours' run at full load does not exceed 72deg. F. above that of the surrounding air as measured by thermometer. The generator either serves the requirements of the power station motor plant, etc., or supplies high-tension three-phase current to the transmission lines on light load as may be required.

High-Tension Switchboard.

The main high-tension switchboard is of the Ferranti type, and is an example of the serviceable adaptation of this firm's well-known gear for multiphase work. The framework consists of heavy slate panels, grouted directly into the wall, with vertical slates dividing the whole into a number of recesses into which the various parts are fitted. When extended for the full capacity of the station, the board will consist of 17 panels in all—namely, six generator panels, one motor-generator panel, two wattmeter panels, and eight feeder panels. Each generator panel contains three fuses, three switches, and three ammeters, and provision is made for disconnecting any panel from the bus bar when alive by means of insulating tools. 'Bus-bar, voltmeter, and synchronising gear in duplicate is provided at the top of the board. The two wattmeters are required for receiving the respective outputs of the two companies. The three-phase switches on the generator panels are of the oil-break type, as are also the fuses, which latter are provided with duplicate contacts and cable receivers. A regulating table under the high-tension panels contains for each three-phase generator a handwheel connected to an "open type" regulating resistance placed in the basement below, an ammeter indicating the current through the field of the alternator, and a double-pole carbon-break switch constructed for a working pressure of 250 volts. Very ample provisions, as previously reported, have been made under the switchboard platform for the regulating resistances and cables leading up to the cable receivers. The circuit panels are of a design similar to the generator panels, with the exception that the switches, being for a smaller capacity, are of the spring-break type without oil. Each phase is in a separate compartment, and the switches for each machine and circuit are distinguished, to prevent the accidental operation of the wrong switch, by extending the division plates between each set of three panels, and by colouring the front edge of these plates white. The board is a good example of Messrs. Ferranti's high-tension

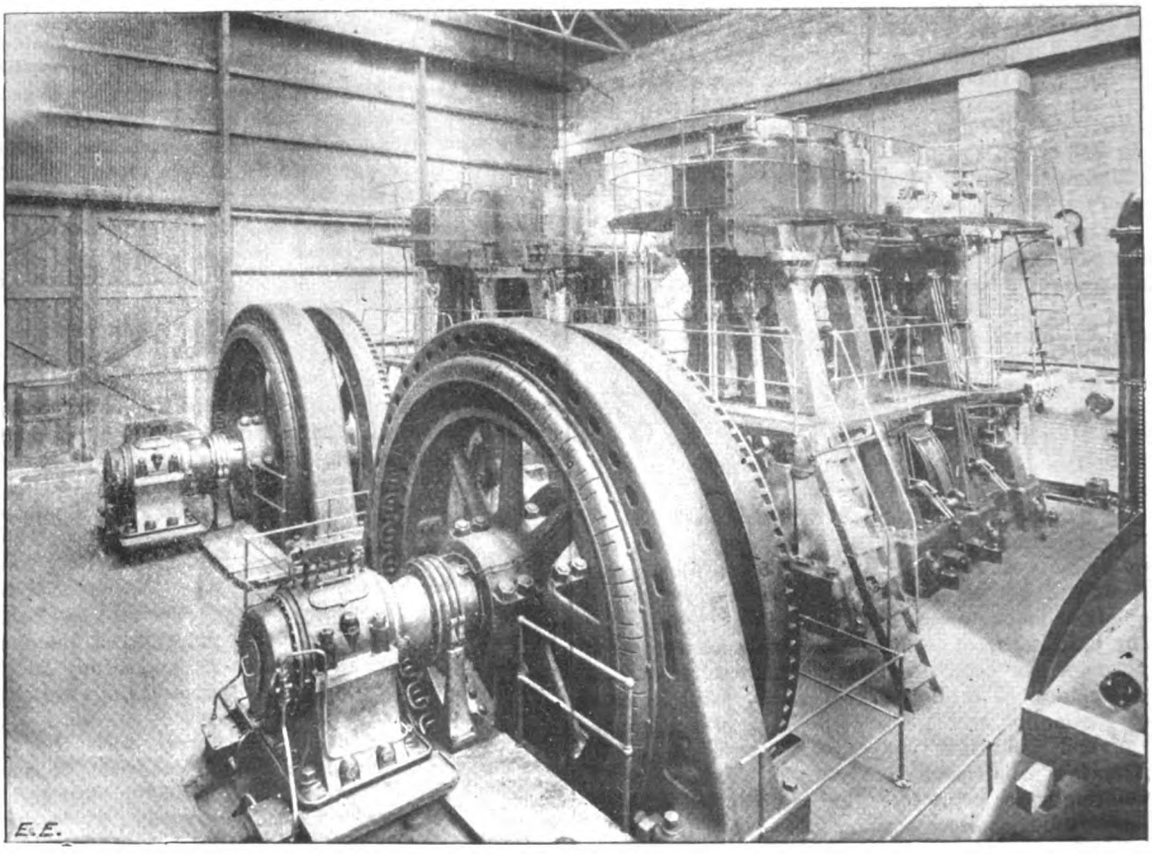

FIG. 9.—Two of the Wigham-Richardson 1,400-i.h.p. Sets and B.T.H. Alternators.

Digitized by Google

switchboard work. Fig. 10 shows the connections to both the high-tension and low-tension boards in diagrammatic form.

Low-Tension Switchboards.

The low-tension switch gear comprises three boards, two being on the floor-level of the engine-room and one on the switchboard gallery. These boards control the two 200-kw. Belliss sets, a small exciter set, and the 150-kw. motor-generator. One of the boards on the floor level holds the main dynamo fuses, the compounding switches, and the field switches. The main low-tension board is on the gallery, and contains three sets of 'bus bars—namely, station power and lighting 'bus bars, exciting 'bus bars, and feeder 'bus bars. The station 'bus bars and exciting 'bus bars are arranged one on each side of the system, so that the station power and lighting circuits and the alternator exciting circuits are each operated quite independently at 250 volts. In this way the exciting circuits are kept entirely distinct from anything else, thus greatly reducing the liability of any mishap to the excitation. Double-throw switches are provided by which any generating set can be thrown on to these 'bus bars or on to the feeder 'bus bars. The feeder 'bus bars are connected through a wattmeter panel to the feeder board, which is arranged for four sets of three-wire feeders, and also includes a traction panel for the supply of power to the shunting locomotives in the yard outside.

Test Pond.

A test pond has been constructed outside the station for periodically testing the various generators. The arrangement consists of three plates of lead immersed in a brick pit filled with water. Each plate is separately suspended from a rope passing over a pole carried on a wooden staging above the pit. Three windlasses are provided at a safe distance from the pit, by means of which each plate can be raised and lowered independently, and thus the load can be readily balanced and adjusted. Overhead wires connect these plates with terminals fixed on the wall of the switchboard gallery, from which temporary connections are made for testing any of the three-phase or continuous-current generators, the pond being of sufficient capacity to absorb 1,500 kw. at 5,500 volts. During the construction of the Neptune Bank power station Mr. H. L. Rieeley has held the post of resident engineer.

Mains.

The whole of the main work, with the exception of that portion of the high-tension transmission line between Manors sub-station and Gosforth (see Fig. 2), was executed by the Callender Cable and Construction Company, Limited. There are two essentially different types of mains employed, the first consisting of three-core cables intended to be used on the three-phase circuits and the second of single-conductor cables separately insulated, each one laid by itself on the solid system. The three-phase mains consist of a series of three-core cables, each branch having a sectional area of ·15 square inch, insulated by bitumenised paper. The three cores are stranded together and wormed circular, and on the cable thus formed there is an additional thickness of bitumenised paper so as to bring up the wall of dielectric to the same radial thickness between any conductor and earth as it is between the conductors themselves. The cables thus made are designed to comply with the Board of Trade regulations for working at 6,000 volts effective, even if with no point earthed. The cables which also have a lead sheathing are laid on the solid system in cast-iron troughs supported on wooden bridges, and run in with Trinidad bitumen. The trough is finished by a wrought-iron lid, consisting of ¼in. plate, so as to give the greatest possible mechanical protection in case of accident from the outside.

In order to reduce the possibility of interruption to a minimum, two separate and distinct lines of high-tension mains are run from the power-house, occupying throughout separate trenches. Where they both make use of the Hadrian-road one set of mains is laid on the north side and the other on the south side, but in all other streets in the district the duplicate mains are carried in separate trenches. One three-phase main goes direct to the sub-station at the North-Eastern Marine Company's yard. Another similar main is carried to the sub-station at the Tynemouth end of the district, whilst a third main is laid with connections to both these sub-stations, so that it can supply current from the generating station to either or both, or be used as an interconnecting main between the two sub-stations. Spare ways are laid wherever high-tension mains are put down, and in addition there is a series of telephone and test cables, so that any sub-station

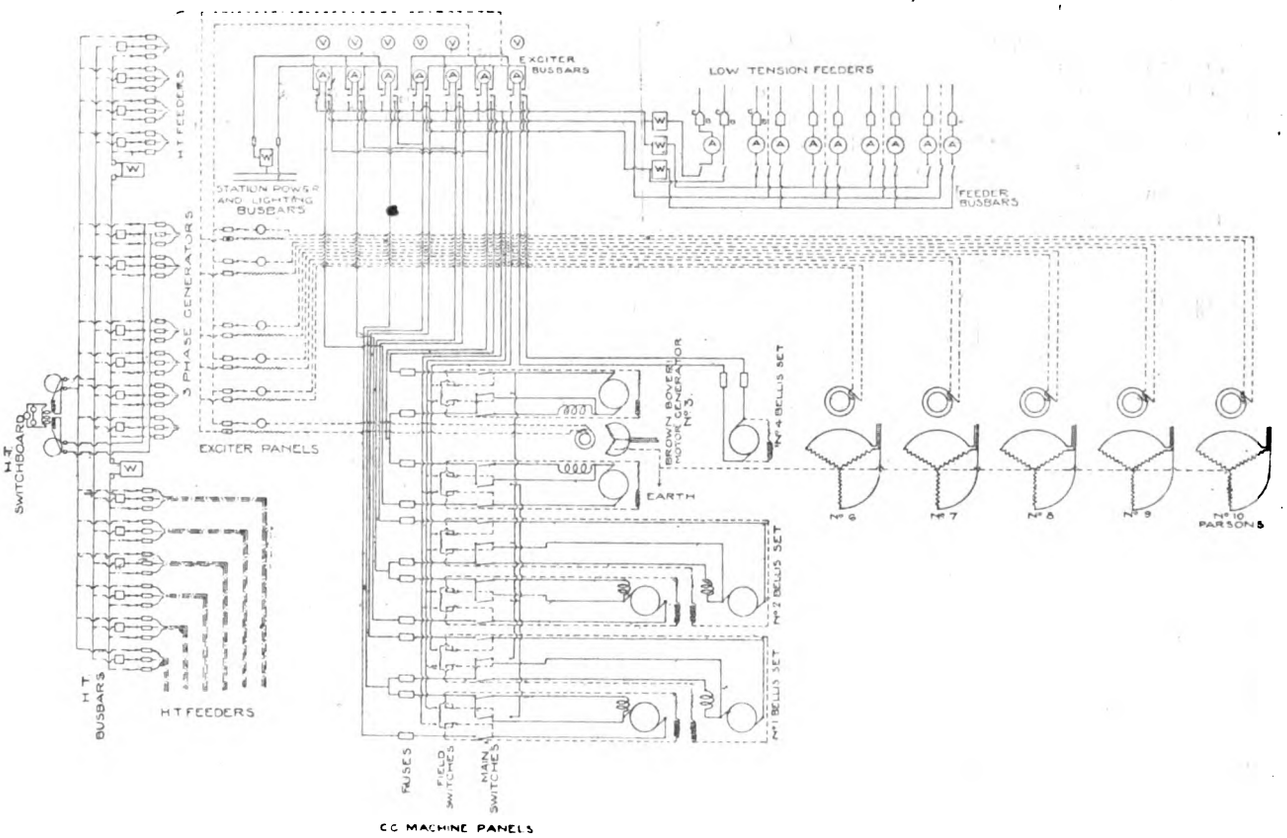

FIG. 10.—Diagram of Switchboard Connections, Neptune Bank Power Station.

Digitized by Google

is in immediate communication with headquarters and with its neighbour.

The low-tension network consists of the Callender Company's standard make of vulcanised-bitumen cable. The mains are three-wire, consisting for the greater part of ·5, ·25, ·5 square inch conductors, but in some cases ·5, ·5, ·5 square inch is used. Each cable is laid in an earthenware trough by itself, supported on bitumenised wood bridges, and run in solid with refined Trinidad bitumen, being completed by a covering of hard bricks which are set in the molten bitumen. These low-tension mains run from the generating station along the Hadrian-road to the North-Eastern Marine sub-station. They are also laid in Station-road, Wallsend, and along the High-road, looping back into the main distributing line between the power-house and the sub-station. In addition to this line, there is a network of similar low-tension mains in the Willington Quay district, and low-tension connection is made between networks by means of vulcanised-bitumen feeders running from the North-Eastern Marine sub-station, along the North-Eastern Railway line, crossing the Willington cut viaduct, and there joining the Willington Quay district.

There are several branch distributors of smaller section, and, practically speaking, it may be said that the system is laid out so as to supply any of the factories with either high or low tension current as they may wish. A series of iron pipes has also been laid along the North-Eastern Railway between the power-house and Messrs. Armstrong's for the purpose of supplying them and others with high-tension three-phase current. Briefly put, this is a description of the feeder and distributing network in the Walker and Wallsend district, from which it will be gathered that the main sub-stations are interconnected both on their high and low tension sides, but while the interconnector is, in the latter case, only intended to be used on very light loads, the high-tension connecting cables are, on the other hand, of the same section as are the main high-tension cables from the generating station.

In addition to the above described work, the Callender Cable Company are now busy with the construction of a heavy trunk line to connect the generating station at Neptune Bank with Newcastle City. Their contract provides for the construction of a conduit having nine ways each 4in. in diameter, consisting of specially-made stoneware pipes set in a solid block of concrete, into which three-phase cables will eventually be drawn. These cables will be manufactured by the Callender Cable and Construction Company, and will be in many respects the same as the three-phase mains laid in the Walker district but the sectional area of conductor in each branch will be considerably larger, being ·25 square inch, whilst over the lead cover there will be a sheathing of steel wires so as comply with the new requirements of the Board of Trade as to the conductivity of earth sheathing wherever three-phase high-pressure current is dealt with. The trunk main conduit in question starts at the generating station at Neptune Bank, and runs *vid* Walker-road, through Walker, to the sub-station at the end of Byker Bank. It proceeds thence to the sub-station at Manors, where it terminates. This is to act as a trunk for the supply of current required in Newcastle City, and, except at the various sub-stations, it is not intended to be tapped or interfered with.

FIG. 11.—Laying Callender Mains in Newcastle.

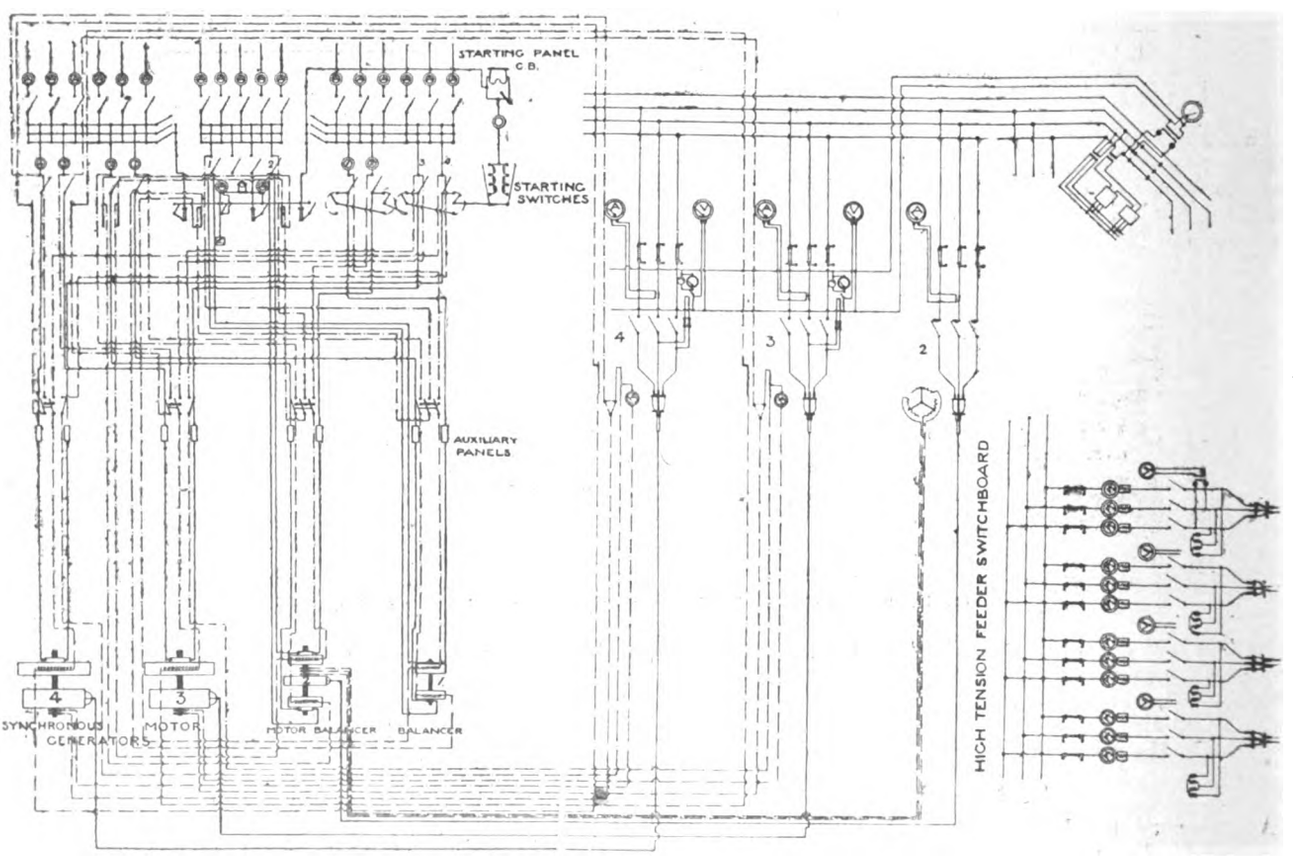

FIG. 12.—Diagram of Switchboard Connections in Manors Sub-Station, showing L.-T. Connections on left and H.-T. Generator Connections in centre.

Along a great part of the road a system of three low-tension mains has also been laid, and it is eventually intended to connect up any portions of this network which at present are not placed in position. This low-pressure network consists of single-conductor cables of the Callender Cable and Construction Company's standard make, insu-

Digitized by Google

lated by vulcanised bitumen and laid solid in Trinidad bitumen precisely as used in the Wallsend district, with the exception that instead of adopting three single troughs, one for each cable, a special form of three-chase troughing has been used with the view of economising space.

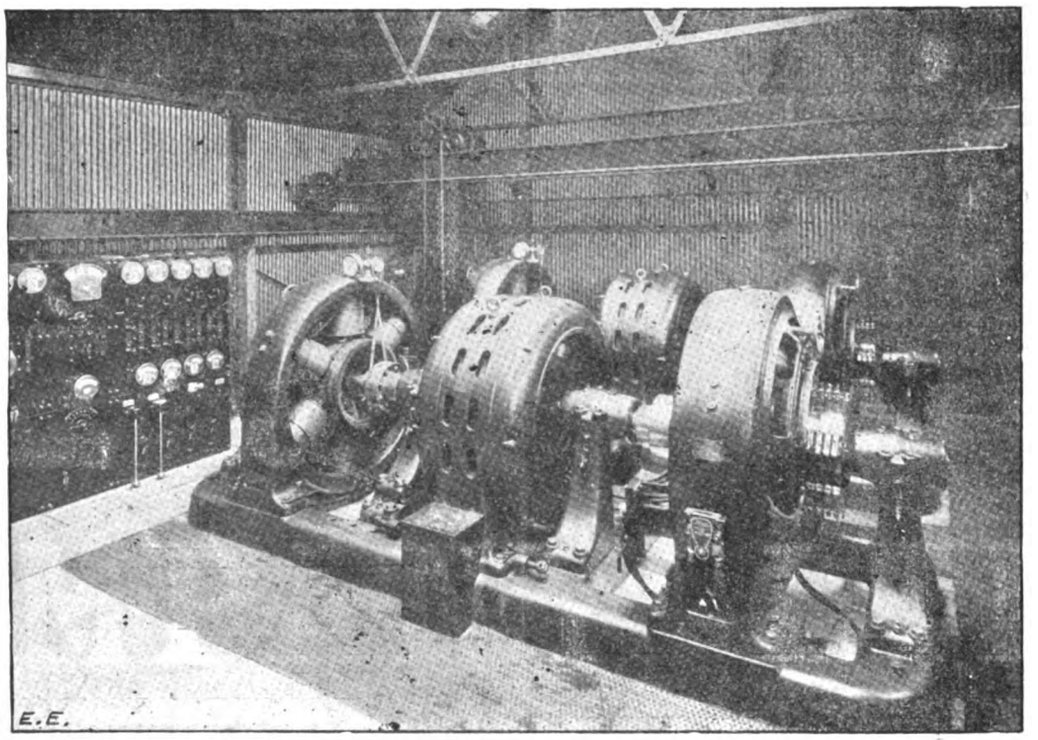

FIG. 13.—Sub-Station near North-Eastern Marine Engineering Company's Works, showing 300-KW. B.T.-H. Motor-Generators.

Throughout the whole of the work on both contracts great care has been taken in regard to the manholes and drawpits. On the Wallsend and Willington line, owing to the difficulties met with and the nature of the subsoil, and the fact that the mains are in the roadways, these are practically small underground chambers. The mains forming the Newcastle trunk line are all laid under the footpath, and consequently the manholes, although larger in superficial area, are not quite so deep. They have been constructed with the view of making it possible to handle the heavy trunk main cables and connect them up as readily as is possible; and although they form an item of considerable expense in the total work, they are probably the best examples of manholes on a heavy drawing-in system which have ever been constructed in this country. The boxes joining the factory lengths of high-tension mains are designed so that there shall be complete continuity of the wire sheathing. They are of a type which has been proved satisfactory in practical working at Wallsend among other places. The disconnecting boxes used on the low-pressure mains are single-pole, and are so arranged as to be readily accessible, but at the same time are kept perfectly watertight through the special design of the lid. The feature in the whole of the boxes in Newcastle and its district is the interchangeability of all parts, everything being made to template, and as few types as possible being adopted.

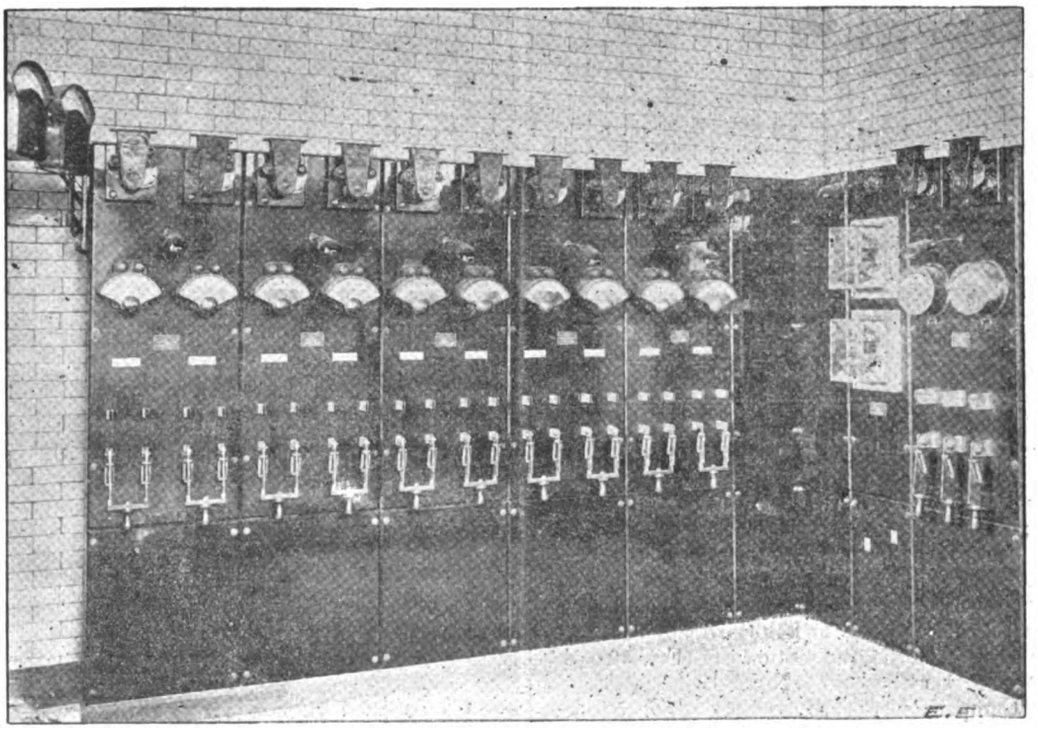

FIG. 14.—View of North-Eastern Marine Company's Sub-Station Switchboards.

Digitized by Google

The Callender Cable Company have had a large staff in Newcastle for more than a year past. The Walker and Wallsend work has been carried out under the supervision of Mr. George Marsh; the Newcastle trunk main is in the hands of Mr. F. B. Collard; whilst other work which they are doing in Newcastle City, in Jesmond, and in Walker is in the hands of one or the other of these gentlemen, or of Mr. Fase. Fig. 11 shows the work of laying Callender mains in progress.

The high-tension transmission cables between the Manors sub-station and Gosforth are being supplied and laid by the British Insulated Wire Company. These cables are of the above company's well-known three-core, clover leaf type, each core having a sectional area of ·25 square inch. The requirements of the Board of Trade as to the conductivity of earth sheathing are met in the case of these cables by providing just under the lead cover a continuous layer of copper tape.

Main Sub-Stations.

With regard to the main sub-stations, these are practically identical in design, the only difference being in their over-all length, which was effected by the available site area, but even this difference is only slight, and it may be said that each has a length of about 80ft. and a width of 35ft., being designed for an eventual capacity of 2,000 kw. in synchronous motor-generators. The present equipment of each may be enumerated as follows: two 500-kw. synchronous motor-generators; one 75-kw. asynchronous balancing set; one 25-kw. continuous-current balancer.

Having regard to this uniformity in the design of the main sub-stations, it will suffice for our purpose to take one example only—namely, the Manors sub-station, which is equipped as described. The switchboard connections in this station are shown in diagrammatic form (Fig. 12).

The sub-station serving the North-Eastern Marine Engineering Company's works contains two 300-kw. motor-generators by the British Thomson-Houston Company, Limited. One of these sets is shown in Fig. 13. Each set consists of a synchronous motor wound for 5,500 volts direct coupled to two compound-wound continuous-current machines, one at either end. The output of each of these continuous-current machines is 150 kw. when running shunt at 400 revolutions per minute, the voltage in this case being 265 at full load. Running as compound-wound machines they give 257 volts each. The combined commercial efficiency of each set when running at normal full load is not less than 87 per cent., while the temperature rise after 10 hours' run at full load does not exceed 4deg. C. above the surrounding air. The function of these motor-generators is to receive three-phase alternate currents and deliver direct current to the 500-volt three-wire distributing network. The high-tension switchboard in this sub-station was supplied by Messrs. Ferranti, Limited. It consists of five panels—three feeder and two motor-generator. Each panel contains one ammeter, three switches, and three fuses. Any one panel can be disconnected from the 'bus bars while alive by using insulating tools. Duplicate synchronising gear is mounted on the board.

Messrs. Reyrolle and Co. supplied the low-tension switchboard, which contains seven panels, as follows: one positive, one negative, one neutral, two test, and two starting. There is also a "feeder" board, containing the machine switches and ammeters at the bottom and the feeder and distributing mains at the top. A view of these several boards is shown in Fig. 14.

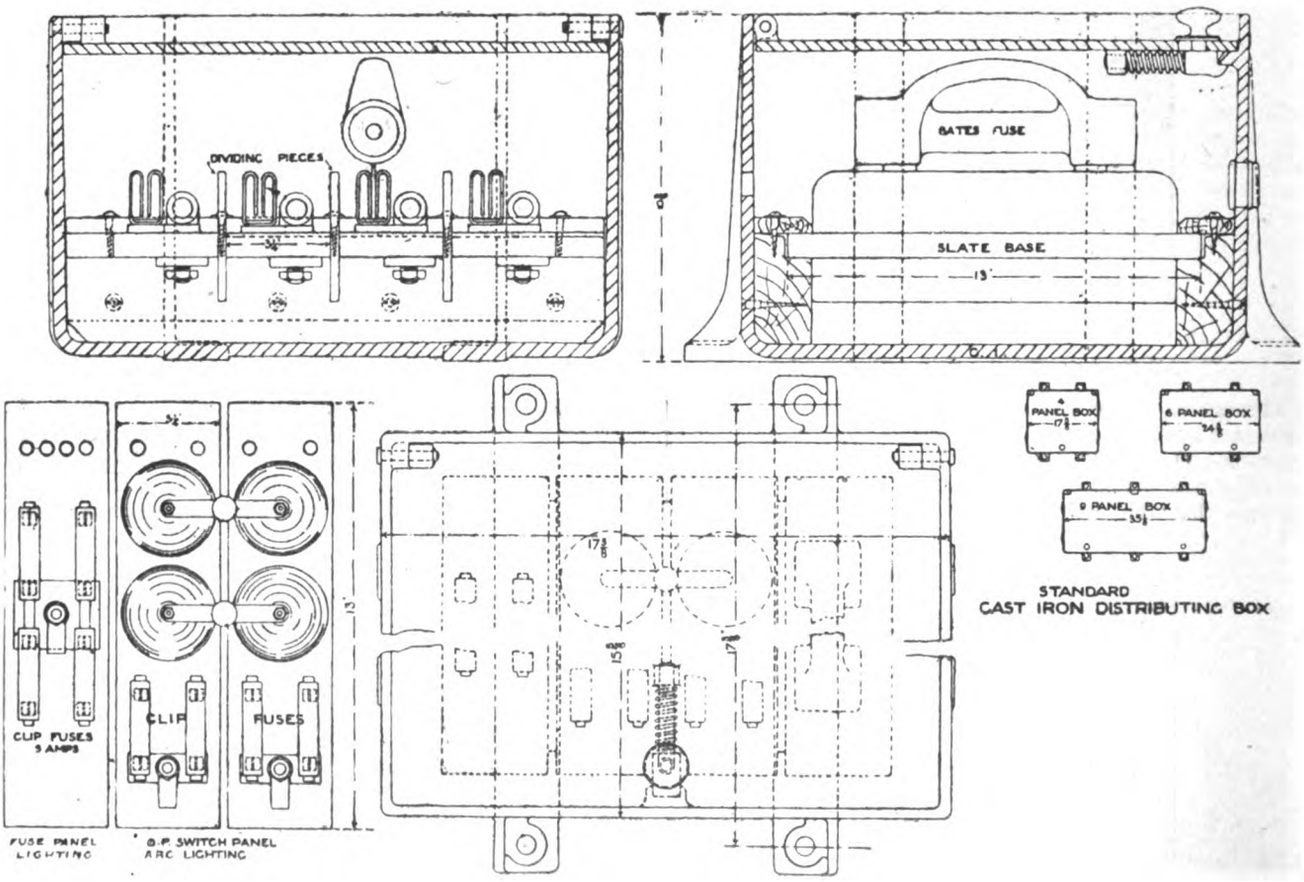

FIG. 15.—Plans and Sections of Works Distributing Box.

A 7½-ton overhead travelling crane, manufactured by Messrs. Morris and Bastert, is also provided. From this sub-station the North-Eastern Marine Engineering Company, Limited, will be supplied with from 1,600 h.p. to 2,000 h.p., exclusive of the demand for lighting purposes.

In some instances a three-phase supply is given. This is notably the case in respect to the Walker Shipyard, owned by Messrs. Sir W. G. Armstrong, Whitworth, and Co., Limited, whose installation may be briefly described. Here also Messrs. Ferranti, Limited, supplied the high-tension switchboard, consisting of four panels—two feeder and two transformer—each panel equipped with one ammeter, three switches, and three fuses; while Messrs. Reyrolle and Co. supplied the low-tension switchboard, consisting of seven panels—two transformer, one meter, and four three-phase circuit—the transformer and three-phase circuit panels being each provided with three fuses, one ammeter, and a triple-pole switch. In the sub-station are also installed seven British Thomson-Houston 50-kw. single-phase transformers, having a ratio of 5,500 to 440 volts. Of these transformers, one is held in reserve, the six in use being connected up in delta, so that

Digitized by Google

the failure of one unit does not entail a stoppage of the supply. The efficiency of the transformers at full load is 97 per cent. In this shipyard British Thomson-Houston three-phase induction motors are employed. These are of three types, one having a short-circuited rotor, the others former-wound rotors. The former are started by combined oil-break switches and compensators. Of the other types one has a resistance mounted inside the rotor itself, which is cut out by means of a sliding handle passing through the hollow rotor spindle. The other is provided with slip rings, and used in conjunction with a controller for variable-speed purposes. All the works distributing boxes are of the standard design shown in Fig. 15. They are made of cast iron in different sizes, suitable for taking from three to nine panels each, and are equipped with either power or lighting circuit panels according to requirement, the over-all dimensions of the various classes of panel being identical. To guard against risk of a short-circuit in a power distributing box—*i.e.*, boxes equipped with fuses of over five amperes capacity—single-pole boxes are used. About 400 h.p. of plant is installed in the Walker Shipyard.

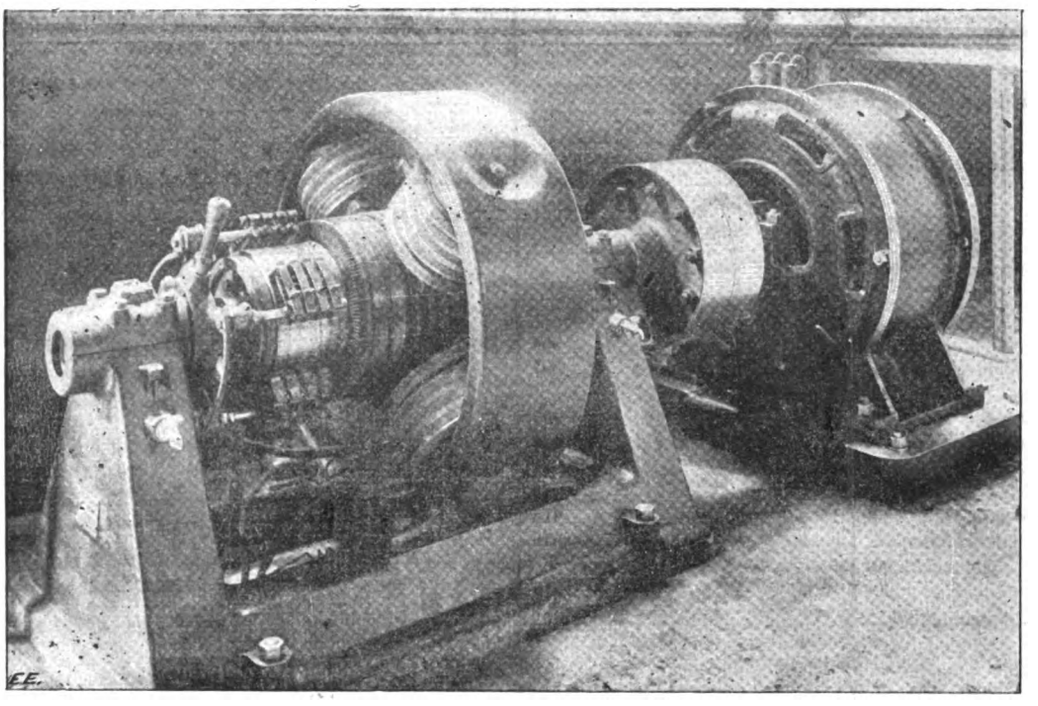

FIG. 16.—75-kw. Brown-Boveri Motor-Generator, Northumberland Shipbuilding Company

In the Northumberland Shipbuilding Company's works sub-station there is installed a 75-kw. motor-generator, manufactured by Brown-Boveri and supplied through Messrs. Richardson, Westgarth, and Co. It consists of an asynchronous motor coupled direct to a 240-volt and direct-current generator, and is illustrated in Fig. 16. There are also four 75-kw. single-phase transformers by the British Electric Transformer Manufacturing Company, having a ratio of 5,500 to 440 volts. Three are in use and one spare.

THE VISIT TO GERMANY.

After a considerable amount of discussion as to how we can best assist in making the visit of the Institution to Germany conduce to the aid of British theory and practice, we have determined to offer

Two Prizes—
One of Twenty Guineas,
One of Ten Guineas,

for the best essays descriptive of the visits paid, comparing the points of detail which may prove of advantage to British manufacturers and organisations, duly considering the conditions under which our home work is carried on. If more than two essays are thought suitable for reproduction, those used will be paid for at our usual rates for contributions. The editors of the *Electrical Engineer* will decide the order of the essays, and their decision will be final. The length of the essays should not exceed fifteen or twenty of our columns. The moving idea for the above is to be found in Bacon's essay on "Studies," wherein he says, "Reading maketh a full man; conference, a ready man; and *writing, a correct man.*" We are anxious to assist in getting "correct men"—hence our offer.

MUNICIPAL ELECTRICAL ENGINEERS.

Glasgow in this year of grace is the city of congresses. At the present time, like the early swallows, they are numbered by units; by-and-by they will be counted in swarms. The Association of Municipal Electrical Engineers is at present sitting in convention in the city of St. Mungo under the presidency of Mr. Chamen, the respected electrical engineer of Glasgow. We assume in our eulogy of the presidential address that the association has nothing to do with the theoretical question of municipal trading, but exists upon purely business lines. The purpose for which its members live is to do the best they can, from a business point of view, for the municipalities under which they serve. Thus the main object of each of these annual conventions is to discuss the question, How best can we improve our business? The address of Mr. Chamen, looked at from this point of view, is most excellent. He analyses the systems of charging for current, the conditions under which current is supplied, giving his conclusions dispassionately but most emphatically; and, really, it is difficult to see that they can be effectively challenged. As the whole address is given elsewhere, it will not be necessary to discuss it at any length. After a preliminary mention of the hardships of having to pay into a sinking fund practically before works are in existence—a hardship which few or none will be found to deny—he deals with the main subject of his address—the best method by which to charge for current. There may be nothing very new in the subject matter, but certainly it is presented in a somewhat novel fashion, and the author is confident enough to say that the conditions under which current for lighting purposes is supplied are somewhat peculiar, and to conclude that the charges must

Digitized by Google

be characteristic also. If we understand the argument aright, the moral is that the true charge for current supplied is decided by the state of the load curve at the time that current is supplied. It is the old, old song sung in a new setting. A few sentences point to a remedy, but as yet the necessary apparatus to remedy this great defect is not forthcoming. The curve of generation as regards gas is fairly constant; the curve of supply is as fluctuating as that of electric current. The difference, from a business point of view, is that one can be stored while the other cannot. Invention as regards electrical storage is no doubt in a parlous state, but he would be a bold man who should say it was dead, and that the world is not destined to see some inventions sooner or later that will render it effective. Mr. Chamen is to be heartily congratulated in putting before the members so clearly and succinctly a subject which is of the first importance to them all. He certainly realises the existing conditions, but while his solution may be the best it may not always be expedient in practice.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

GILBERT'S SELF-DRIVING WEIGHT OSCILLATING MOTOR.

SIR,—*Re* Mr. G. Evans's letter in your issue of 14th inst., neither he nor our greatest expert in science (Lord Kelvin) would say, after seeing my latest design of motor, it was "folly persisting further," but as I have arranged to ventilate it in another paper, owing to your lack of enterprise, Mr. Evans may feel disappointed in not having another opportunity to criticise in your journal. As to his notion that the motor should work on a vertical axis, it will do nothing of the kind, but will do so perfectly on a horizontal axis, and without ball bearings. I may mention I have to-day received my first model, weighing about 1cwt., from Messrs. Braun and Co., mechanical engineers, King's Cross, London, but unfortunately with several of the parts badly twisted in transit. This accident will put me back a bit, I'm sorry to say. Mr. Evans may as well say it is folly trying to fly, but my candid opinion is that it will be done, and that it is a much more intricate problem than to cause a wheel to revolve without any external aid. Please use the correct title of my machine as given above, as I have nothing to do with perpetual motion. My machine will work as long as a steam-engine. Nothing more could be desired.—Yours, etc.,

ARTHUR E. GILBERT.

Heaton, June 15, 1901.

[N.B.—We much regret that Mr. Gilbert's motor had parts twisted in transit.—ED. *E. E.*]

PREECE'S WIRELESS TELEGRAPHY.

SIR,—With reference to your interesting article on the above in your last issue, possibly you could allow me to put forward one or two suggestions for its possible improvement. If your map showing the position of the circuit on the Rathin Island and the mainland is correct, then it would appear that the paralleling of the two wires is *not* by any means the best. I should take it that the perfect paralleling of the wires would be one of the first essentials to the successful working of the system, so that the electric waves passing off at right angles from one wire would meet the other wire at right angles, and be picked up by them. The better the two wires run parallel with each other, the better would be the action at the receiving wire.

Another suggestion is that the two copper wires should be nickel plated or galvanised, say, every alternative yard or two yards—that is, one or two yards plated, then one or two yards bare, then, again, one or two yards plated, and so on. Or, better still, have two wires on the island and two on the mainland, one wire to be of pure copper and the other nickel-plated, or a galvanised copper wire, the copper wire to act as a transmitter, as unquestionably copper is the best for such purposes, and the plated wire to act as a receiver. The electric waves from copper would more powerfully and promptly affect any white metals than copper upon copper only. In fact, all electrical work is more or less confirmation of this idea—instance the electric cell, the dynamo, Marconi's wireless telegraph, etc., wherein one metal affects an electrically opposite metal.

Possibly, if the above suggestions were put into practice, the receiving current would be sufficiently improved to affect a galvanometer, or very sensitive electric bell, on the Rathin Island installation.—Yours, etc.,

GEO. H. SMITH.

37, Daniel-street, Cardiff, June 17, 1901.

N.B.—Could you or any of your readers inform me where I can obtain particulars by post of the "*Nobel*" *prizes* that were bequested by the late Dr. Nobel, the inventor of dynamite, etc, and which prizes are offered for four or five of the greatest inventions in the sciences and arts. I am anxious to become a competitor, hence my enquiry. A reply will oblige.—G. H S.

FORTHCOMING EVENTS.

FRIDAY, JUNE 21.

Municipal Electrical Association.—Third day of the annua convention at Glasgow. The meeting closes to-morrow (Saturday).

SATURDAY, JUNE 22.

Institution of Electrical Engineers.—Visit to Germany.

Sports.—Annual sports in connection with Messrs. Crompton and Co.'s Arc Works at Chelmsford.

FRIDAY, JUNE 28.

Physical Society.—At 5 p.m., ordinary meeting in the Wheatstone Laboratory, King's College. Papers: "The Effect of a High-Frequency Oscillatory Field on Electrical Resistance," by Mr. S. A. F. White; "The Spectrum of Cyanogen," by Mr. E. C. C. Baly and Dr. H. W. Syers.

Society of Arts.—At 9 p.m., annual conversazione at the Royal Botanical Gardens.

TYNESIDE ELECTRICITY WORKS.

(Concluded from page 897.)

The British Thomson-Houston Company, Limited, did all the switchboard work in connection with this installation, besides supplying the motor equipment of the works. There are eight spur-driven winches, the electrical equipment of each consisting of a three-phase induction motor with necessary controlling gear and resistance, the whole gear being entirely enclosed by sheet-iron covers. Each winch is capable of lifting three tons at 50ft. per minute, and capable of running in either direction at varying speeds, all motions being controlled by one handle. The cables to the various winches are laid underground in wood troughing, and run in with bitumen to guard against injury. The lighting of the works is on the 240-volt two-wire system, and consists of 50 arcs and about 250 incandescent lamps. This installation represents an aggregate of about 400 h.p.

Another considerable installation is that in Messrs. Wigham, Richardson, and Co.'s Shipyard and Engineering Works, the overhead transmission lines to which are shown in Fig. 17. This comprises a motor-generator of 75 kw. capacity, and transformers of 110 kw. capacity, supplied by Brown-Boveri through Messrs. Richardson, Westgarth, and Co. The works plant includes four three-motor overhead travelling cranes, dealing with 14, 10, and 6 tons respectively. There are also 50 five-ampere Angold enclosed arc lamps—two in series on 240 volts—and over 500 incandescent lamps distributed about the works. The plant connected, exclusive of this lighting load, aggregates

Digitized by Google

500 h.p. It may be mentioned that the erection of the plant in each of the motor installations described was carried out by the British Thomson-Houston Company, Limited.

In addition to the motor load already connected, which, it will be gathered from the foregoing, aggregates some 3,000 h.p., and prospects of a further demand in the same direction, there will be also the area at present supplied from the company's alternate-current station at Pandon Dene to provide for. The high-tension transmission line to Newcastle for this purpose is already in hand, as mentioned elsewhere, and a low-tension three-wire network of mains will be gradually laid over the area, while at the same time the generating station at Pandon Dene will be converted into a main sub-station similar to the one already described, whereby the existing supply will be ultimately displaced by a low-tension continuous-current supply. The cost of conversion is estimated at the rate of 2s. 9d. per lamp connected. Thus it will be seen that, besides a very promising day load represented by the power installations on Tyneside, a large night load is also ready to hand, there being the equivalent of between 70,000 and 80,000 8-c.p. lamps connected in the company's Newcastle area.

The future policy of the company further embraces a proposal to construct a system of electric tramways, as shown on the accompanying map (Fig. 18). It will be seen that the intention is to join up to the Newcastle Corporation tramways at three points on the Newcastle side and to the system worked by the British Electric Traction Company on the Tynemouth side, thus connecting these two systems by means of a link running through a sparsely-populated portion of the company's area of supply. No doubt such a scheme would incidentally lead to the opening up of this sparsely-populated district for building purposes, etc. It should be mentioned, however, that the sanction of Parliament to this scheme has yet to be obtained. When complete, the undertaking, should, therefore, contain that element most conducive to the success of such a scheme—namely, a satisfactory load factor. With cheap coal into the bargain—5s. per ton being about the average price, we believe—and other natural advantages of position, etc., there should be little doubt as to the ultimate success of the supply from a financial point of view.

With regard to the large power plants supplied with energy from the company's mains, it may be mentioned that the company undertake to bear the initial cost of installation and to maintain the plant in consideration of a charge at the rate of 15 per cent. per annum on the initial outlay. Of this 15 per cent. one-third represents interest on capital outlay; another third, rental of the installation; and the remaining third, depreciation. After a period of 20 years the installation becomes the holders' own property. In other ways the company are encouraging the use of electricity as a motive power, and, amongst other things, will endeavour to displace the steam-hammer so extensively used in the district by one using compressed air supplied from a motor-driven compressor. When in Newcastle recently we saw one of these air-hammers at work, and so far as we could judge, its action and control left nothing to be desired. There is undoubtedly a wide field for the use of electrical power in this direction, especially around Newcastle, and no doubt there will also be less steam wasted at some of the surrounding collieries as the supply of cheap electrical power becomes available.

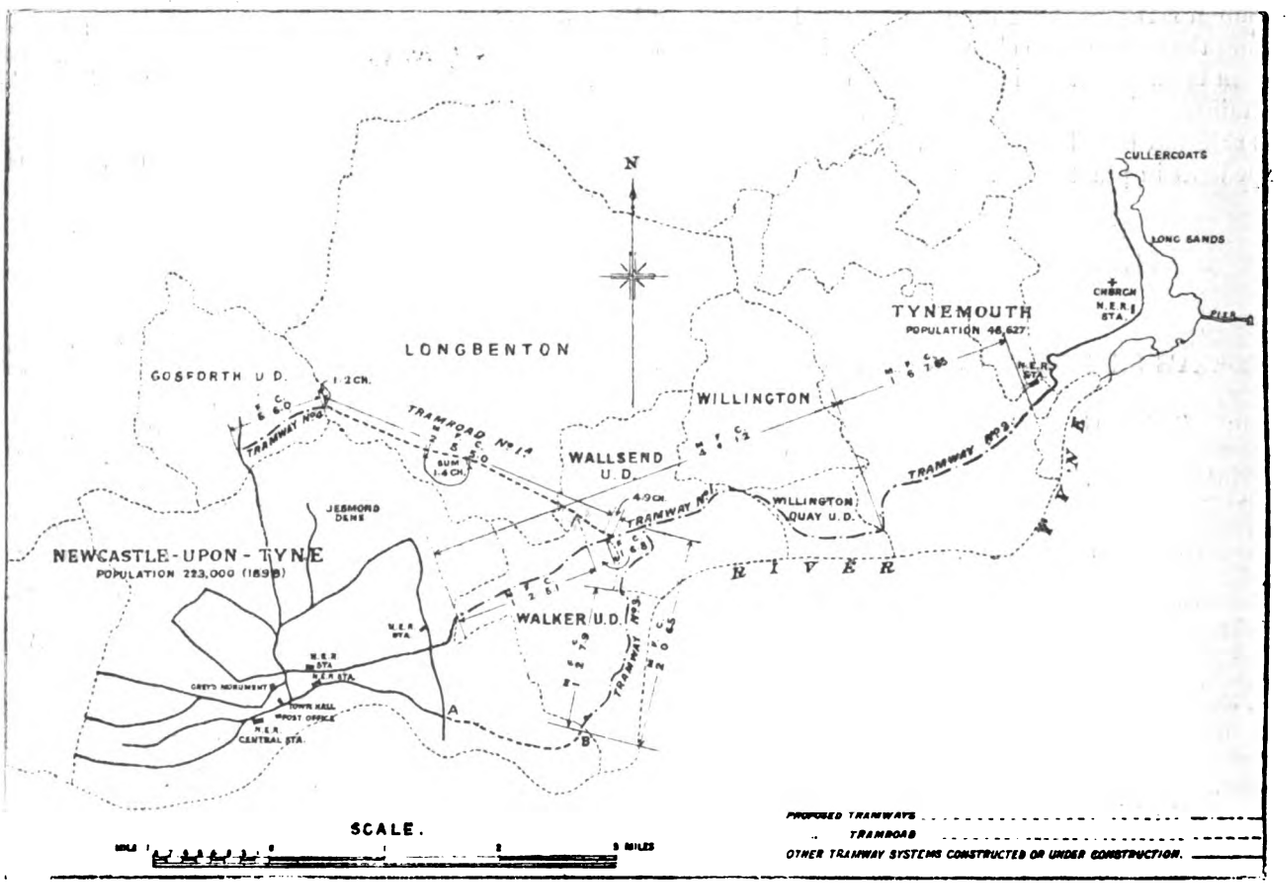

FIG. 18.—Map of Proposed Tramways.

In conclusion, we have to thank the consulting electrical engineer, Mr. Charles H. Merz, and some of the principal contractors concerned for their courtesy in placing at our disposal the particulars given above.

Opening Ceremony.

The formal opening of the above-described works by Lord Kelvin duly took place on Tuesday last, when a special train conveyed a large number of guests to Carville Station, where carriages were ready to take them to Neptune Bank power station. An inspection of the power station and various installations supplied with power, including that belonging to the North-Eastern Marine Engineering Company, was then made. Sir Andrew Noble presided at the luncheon subsequently given at the Drill Hall, Walker. In declaring the electric supply, Tyneside, open, Lord Kelvin said the beginning witnessed that day was on a scale which a few years ago would have been considered very large, but which the Newcastle Electric Supply Company now regarded as only a small part of what they were going to do. They

Digitized by Google

had seen the North-Eastern Marine Engineering Works using low-pressure continuous current. They would understand that there might be a reason for choosing continuous-current motors. A great deal of work had to be done at various speeds, and the machines must go fast or slow. That, he believed, was the governing reason. In the present state of electric practice it was not quite so easy to run a three-phase motor exceedingly slow, and at all different speeds, up to the maximum speed with good economy. The Northumberland Shipbuilding Company's yard was interesting, because all the power work done in it was by three-phase motors. Although they had known for years that the three-phase motor was an exceedingly good thing, not many of them had seen much of it at work. It was interesting to note that the three-phase system of distribution gave absolutely fair play to either direct current for the lighting of towns, and for the use of small motors, or for the largest motors. A great boon had been conferred on Great Britain by the work that was now inaugurated.

MUNICIPAL ELECTRICAL ASSOCIATION.

Glasgow Congress.

The sixth annual congress of the Incorporated Municipal Electrical Association was opened in Glasgow on Wednesday last. The president, Mr. W. A. Chamen, took the chair at 10 a.m. at the Institution of Engineers and Shipbuilders in Scotland, and introduced the Lord Provost of Glasgow to the members present.

The LORD PROVOST extended a hearty welcome to the members of the association to Glasgow on behalf of himself and the City Council. They recognised the valuable work done by the association, and the importance of keeping electrical undertakings in the hands of municipalities. He believed that the supply of electrical energy from central stations was still in its infancy, and that they had hardly yet crossed the threshold of the large and valuable field over which electricity would have to be supplied in the future. He wished the association an even richer and wider success than they had yet achieved. As regards Glasgow, they hoped that the good weather for which that city was noted would continue, but in any case the hospitality of the city would be extended to the members of the association.

Mr. W. A. CHAMEN then proposed a vote of thanks to the Lord Provost for his kindly greetings and for finding time to come to the first meeting of the congress.

In reply to acclamations, the LORD PROVOST said that they were pleased to find Mr. Chamen elected president of the Municipal Electrical Association. They had in Glasgow a high opinion of their electrical engineer. When the post was vacant the Corporation determined to get the best man, and they believed that they had succeeded in so doing.

Mr. W. A. CHAMEN blushed, and then read the following address:

Gentlemen,—I have to congratulate you upon the incorporation of this association. We are starting into a new century and into a new reign as a newly-incorporated body. Drawing up the memorandum and articles of the association has been a work of great labour, and has extended over some considerable time. Our hon. solicitor, Mr. Alderman Pearson, has carried the whole matter through for us in a most admirable manner, and we owe him for his toil and patience a great debt of gratitude, which we shall find it hard to repay by anything that we are able to do in return.

On looking over the addresses of the last two presidents, I find that the affairs of the Municipal Electrical Association and its work have been so fully and so ably dealt with, and that so many of the points indicated as requiring attention and providing work for the association still occupy those same prominent positions, that I would ask those of you who were not present at the last two conventions to obtain copies of the *Proceedings* for the last two years from the secretary, if you have not already done so, and to read over those two addresses. I do not propose in this short address to draw your attention to the brief but important history of the Municipal Electrical Association and to its rapid progress, as was so very clearly done by your much respected past-president, Mr. Mountain, to whom so great a measure of the success of this association is due, owing to the unflagging energy he displayed from the start as your first honorary secretary. I have, however, to congratulate you on the further large increase of membership from 77 committee members at last convention to 99, and from 142 engineer members of all classes to 165 at the present time, our present total membership being thus 264, or an addition of 55 since last convention. This increase must be considered most satisfactory, and I think there are indications of a still further considerable increase during the coming year. I regret that we have to record the loss by death of one member—Mr. A. H. Roe, of Bury St. Edmunds.

We have suffered some losses through members resigning their positions as corporation engineers to take up posts with companies or to practice as consulting engineers on their own account. More especially have we to lament in this way the loss of Mr. C. H. Wordingham, who was president, I believe, during the second year of our existence, and who was one of the founders of this association. This is indeed a great loss to us, for the energy and ability which he brought into our meetings was of a kind not easily replaced. Mr. Wordingham was also treasurer of the Benevolent Fund, which owes its existence, I think, almost entirely to his efforts. Though not now one of us, I am glad to tell you that he continues to take great interest in our doings, and he has promised that he will, whenever possible, attend our conventions and join in our discussions. I am sure we will wish him that success in his new departure which he so well deserves.

I have to draw the attention of our associates to the fact that there has not been that enthusiasm displayed by them in sending in papers competing for the prize offered by the association, in consequence of which for the present year the council have been obliged to suspend the award of the prize. This is a matter which I trust will receive your attention, and be discussed at the business meeting on Friday evening.

You will have observed from the programme that there are fewer papers to be read and discussed at this meeting than there were at last year's convention. I believe you will all agree with the council in thinking that it is better to have fewer subjects before us and longer time for discussing them, and that it is more satisfactory for the papers to be read to the meeting by their respective authors than to be held as read and discussed forthwith. The council feel that we are likely to get far more useful discussions in this way, as all present will at least understand what it is that is being discussed.

As already indicated, I do not propose in this short address to touch upon all the subjects which appear to require during the present year the attention of this association, as they have been already so clearly pointed out by your two past-presidents, Mr. Faraday Proctor and Mr. Mountain; but I ought, perhaps, to emphasise one of them—viz., the suspension of payments to sinking fund during course of construction and for two or three years afterwards. Many municipal electrical undertakings are feeling the burden, and, I may say, the unfairness of being taxed during the first few years of their existence, while they are in a state either wholly or partially unproductive of revenue, by being compelled to pay from the start their annual contribution to the sinking fund. While it is, of course, necessary that Parliament should take steps to ensure the paying off of the debt in a proper time, it does seem that it is rather unreasonable to enforce this annual payment from the very start of the undertaking, when it must be so obvious that the concern has had no time or opportunity to bring in a revenue at all proportional to the capital which has been expended upon it. This question is now actively engaging the attention of the council, and I do not know that I need to say more about it here except to point out that it also arises in extensions of existing undertakings into new areas not previously supplied, and which require not only new mains, but new generating stations, and, in fact, a new start and new loans for that specific purpose.

There is, however, one point which has not been touched upon by your two past-presidents, but which I should like specially to bring before your notice. I refer to the question of systems of charging for electricity. Doubtless this is a dry and uninteresting subject, and many of you will think that I might have chosen some engineering point arising out of the experience gained in carrying out the large new electricity works which have been now nearly completed in this city, or in carrying on the supply from these works. Well, gentlemen, that, after all, is what I have done. We engineers naturally love our machinery, our mains, and our whole plant, but we soon find that our attention gets drawn also to other things, and chiefly to that all-important question of money. It is of no use to leave this question to the purely commercial people. If we do so they soon come to us and say, "How is it that you are always asking for more machinery, and thus wanting to increase the capital expenditure? Why won't you get more units out of the plant you have already installed? The undertaking grows it is true, but if you go on at this rate we shall never get the price down. What is the meaning of it?" You all know the answer. The poor engineer has to say, "Well, every winter the maximum load goes on increasing, and we must have the

Digitized by Google

TABLE A.

Class.	Hours.	Number of units used by each class.	Standing charge.	Total coal bills.	Total charge.	Average per unit stated in pence.	Level rate of 1·84d. Total bills.
Street lighting	10½	3,832	£8 3 0	£8 1 10	£16 4 10	1·02	£29 6 10
Public-house	5	1,825	8 3 0	3 17 6	12 0 6	1·57	14 0 0
Restaurant	4	1 460	8 3 0	3 12 11	11 15 11	1·94	11 4 0
Domestic consumer	3	1 095	8 3 0	3 2 11	11 5 11	2·45	8 8 0
Theatre	2	730	8 3 0	2 6 10	10 9 10	3 42	5 12 0
Office	1	365	8 3 0	1 5 6	9 8 6	6 14	2 16 0
		9,307	£48 18 0	£22 7 6	£71 5 6	—	£71 6 10

plant if we are to meet the maximum demand that will be made upon us next December." If the engineer leaves the matter at that, the commercial man goes off grumbling, and saying that "he supposes it can't be helped, and that the electric lighting is a poor business," and so the matter ends for the time being.

Many of my colleagues in this association have, however, not been content to leave this question undealt with, and have set to work to explain that it is only for about three or four months in the year that the machinery is all at work, and then only for a few hours each day at anything like full load, so that the only way in which more units can be got out of the plant is by finding some demand which shall make longer use of it. The commercial people see this, and try systems of discount in order to encourage large consumers, but still the trouble remains, and the engineer gets disliked for pointing out a difficulty and suggesting no remedy. The whole business, therefore, settles comfortably down on his shoulders, and he has in the end to suggest some remedy.

The question of price at first sight seems a very simple matter. Total up the cost of coal, wages, repairs, and petty store bills for the year, and add all the capital charges—*i.e.*, interest and sinking fund—and the management expenses; divide this sum by the number of units sold, and the result is the *cost* per unit. Add to this whatever margin is deemed necessary, and the result is the price per unit. Such a method of arriving at the selling price of electricity possesses one advantage—viz., that it is simple. That, however, seems to be all that can be said for it. It is known to everyone that, as a rule, the greater the quantity of any commodity that can be sold the lower will be the cost of producing it, but the real reason why this is so is understood by comparatively few. There is, for instance, the well-known tale of the old woman who said that she made a loss on every article she sold, and that it was only the quantity of business she did which enabled her to get a living. As she is not commonly reported to have become bankrupt, it is presumed that she had grasped the principle correctly, but was not able to understand the exact way in which it worked, or, at any rate, to properly express it in words. Doubtless she would have lost heavily if she had not been able to sell the quantity she spoke of, and for a sale of half that quantity she might have required to increase the price in order to make any profit, or, indeed, to avoid making any loss, so that up to that point she was correct in saying she made a loss on every article she sold. I do not think this old woman ever sold electricity, but I have no doubt that if that problem had been thrust upon her she would have displayed the same sagacity, and would have adapted herself to the altered circumstances. She might have been a most useful member of an electricity committee.

We may here note a few facts before proceeding. I quote figures from the electricity department of Glasgow as being the readiest at hand. The number of units of electricity sold during the year just concluded (May 31) was, roughly, 6½ millions. The maximum load occurred during November, December, and January at 5 o'clock on each night except Saturdays and Sundays. The plant used (allowing ample spares and stand-byes) if continuously in use at full load would have produced some 81 million units in the year, and this extra 74½ million units could have been sold probably at a profit to the existing consumers if they could have taken it for the low price of about ½d. per unit without any additional capital expenditure or increased management expenses of any kind. Of course I do not suggest that we could ever hope to sell such a quantity as this, but there is a long stretch between 6½ millions and 81 millions, and we might sell more than we do. Let us look a little more closely, though briefly, into some of the figures. The cost of buildings, plant (including spares), and mains, run out at present at about £114 per kilowatt. This figure, of course, varies from time to time, and will go down again when fair proportions become established between the cost of sites, buildings, machinery, and mains, perhaps to £80 or less. It is already down to about £104. This, however, does not affect us just now. The standing charges—being interest, sinking fund, wages, rents, rates and taxes, management expenses, and repairs—amount together to, say, £8. 3s. per kilowatt per annum. This figure is arrived at by taking out the individual maximum demands of the consumers and dividing the total standing charges by the sum of them. You will note that the sum of the consumers' maximum demands is greater than the actual maximum demand upon the generating plant by about 25 per cent., which we may take to mean, roughly speaking, that some 25 per cent. of the consumers either do not come on at all or, at least, not to their full extent until after the time of maximum demand upon the generating stations is past. You will note, therefore, that in apportioning the standing charges per kilowatt due allowance is made for this fact, and the standing charges are less than they would be by about 25 per cent. on account of this diversity factor. This shows the advantage which consumers get by taking the supply from a common source. Let us now consider a few different classes of consumers and see how they use their light, taking in each case their maximum demand, for the sake of argument, as 1 kw., and finding out what number of hours used per day the quantity of units they each consume is equivent to, spreading our investigations, of course, over the whole year. We find the following:

	Hours per day.	Units per annum.
Street-lighting (all night)	10½	3,832
Public house	5	1,825
Restaurant	4	1,460
Domestic consumer (say)	3	1,095
Theatre	2	730
Office	1	365
Total		9,307

These figures are simply examples being easy to follow, but they are not quite accurate. For instance, many of the offices average less than half an hour, while domestic consumers average only about 2½ hours, but we need not worry about fractions for our present purpose. Suppose we had a small concern with these six different consumers as partners. The maximum demand of each is the same—viz., 1 kw.—and the standing charge of £8. 3s. incurred by each, quite irrespective of the amount of electricity consumed, and we have already seen that by combining together this standing charge is reduced below what it would be if each had his own plant, owing to the fact that the theatre does not want light when the office does, and that the domestic consumer also does not fully light up when the others are at their maximum. It seems to me, therefore that these partners as ordinary business men would each agree to pay £8. 3s. per annum in a lump sum plus the working costs according to the number of units consumed in each case.

Let us look, however, at the question of coal. I am obliged to put before you some figures obtained some time ago, which while they certainly would be somewhat less at the present time, will serve for our present purpose. The cost of coal per unit for the various different classes of consumers is greater for the short-hour ones than for the long-hour ones, owing to the waste which occurs in getting up steam for such short runs and in running plant at light loads. From careful tests which have been made, I believe that the following would be about the proportions of the cost of coal for the different consumers:

	Per unit (d).
Street-lighting	·51
Public-house	·51
Restaurant	·62
Domestic consumer	·69
Theatre	·77
Office	·84

These costs include carting and handling of the coal and removal of the ashes, etc.; the street-lighting should really be a lower figure, but no information was at hand at the time the figures were obtained, so that it was put in the same as for a five-hour consumer. (In passing, I may say that during the past six months one-third of the coal we have consumed had been wasted practically through intermittent and varying loads.) If we now make up the accounts for these six consumers, we find they come out as given in Table A. It may be objected that I have not taken into account water, oil, etc., but these are small, and will make no material difference to the result. You will observe that the street-lighting consumer pays an average price of 1·02d. per unit, and the office an average price of 6·14d. per unit, and that the other consumers vary between these two extremes. It seems to me that for lighting purposes this method of looking at the matter is a fair and just

Digitized by Google

one. An electrical engineer of long standing made the following remark in discussing this troublesome question with me some few months ago: "There are," he said, "two principles upon which consumers can be charged. One is that of dividing the total costs for the year by the number of units sold—that is to say, to charge an average price (which works out at about 4d. per unit). The other is that of approximating the charge to each consumer to the cost of supplying him." I think that expresses our position exactly; but which of these principles are we to work upon? I have shown you in a rough-and-ready manner, without any pretence, of course, to a close degree of accuracy, how the costs per unit must vary between very wide limits, and this mostly on account of the very short use which is made of the plant by many of the consumers. If you take out the average cost per unit from the table I have given you, it will come to only 1·84d. per unit. If you charge this uniform price, however, you will be charging the street-lighting with over £29 instead of £16, and the office will be let off with £2. 16s. instead of paying £9. 8s. 6d., and you must remember that in actual fact the proportions of these different classes of consumers are by no means what are given you in this table. Which of us can show one-sixth of our maximum demand occupied in street-lighting and another two-sixths in five-hour and four-hour consumers? If you take my table and adapt it to your own circumstances, I do not think any of you will be able to work out an average of 1·84d. per unit. By using a sliding scale of charge in Glasgow, the cost of producing our 6½ million units in the year just concluded works out at about 3·18d. per unit, or perhaps less, and we have estimated on selling 9,000,000 units for next year at an average cost of production of 2·61d. per unit. The charges are 6d. for the first 365 hours' use per annum of the maximum demand, and 1d. thereafter, with, however, uniform rates of 3½d. for domestic consumers, theatres, and halls, 3d. for churches, and 1½d. for power. Many of our consumers, however, will be paying only about 2d. per unit for lighting under the sliding scale. Do you think we should be able to keep them at 3½d. or, perhaps, 4d., or do you think we should go on increasing our output at the rate of 50 per cent. per annum, as we have done for the last two years, if we reverted to a uniform rate? I am afraid we should not.

Power supply seems to me to be a different question, not simply because it is a day load and in use, perhaps, more in summer than in winter, but because there is no natural law which forces it to come on at a maximum far in excess of its normal at any particular time of the day, a feature which is so very strongly marked in the case of lighting. The diagram shows in dotted lines the total load curve, which includes both electric lighting and power, on a day in last December, and you will observe how sharp a peak occurs about five o'clock. What is the reason of this? It is probably that the very short office load and the early-closing shop load are both just on in addition to everything else. Business men are in signing their letters, and clerks are all hard at work finishing off with the greatest possible haste lest they should be guilty of any unpunctuality in getting away at the usual time. At this time probably every light in these offices is in use, though only for a very short time, for shortly after six o'clock the load is down again to a much lower point. In the summer and during the greater part of the year this does not happen. As soon as daylight draws out to five o'clock this nightmare of a load is gone until next winter. In Glasgow we have a load of this kind to the value of about 1,540 kw.—*i.e.*, we have consumers of the very short-hour class, who require this amount of plant to supply them, and whose average use per day is just half an hour. They consume 248,343 units per annum, which brings in at 6d. per unit the sum of £6,208, or about 3·7 per cent. upon the capital expended to supply them. It is certain that if there were no consumers using current for longer hours than these the concern would become bankrupt in a very short time, even with a charge of 8d. per unit. I need not point out that this five o'clock peak contains practically all our consumers, except churches, theatres, halls, and places of amusement, and domestic consumers to some extent, as they do not light up fully as a rule until later. In fact, all but 25 per cent. are drawing a supply at this time. The conditions under which light is required cause this awkward peak, and they cannot be altered. The proportions of the peak to the whole diagram can, however, be reduced by getting on a greater number of consumers who use current longer. Power supply is a most excellent way of producing this result if we can get enough of it. In Glasgow up to date we have about 1,894 h.p. connected to our mains. It does not cease at five o'clock in the winter, and does not therefore simply fill in our load diagram in the shallow places. If it did this, it might enable us to charge a uniform rate for everybody. It has no peak of its own, however. It goes on from morning till evening with some variations, of course, due to those motors which are used intermittently, but these variations average out in a reasonable way, as there is no circumstance which compels nearly the whole of the motors, whether in continuous or in intermittent use, to come on together either at five o'clock or at any other time. If we had a power load only to deal with there would not be this peak trouble, and it would seem possible, saving only that a maximum charge of, say, £2 per annum should be made to cover interest on cost of meter, etc., to do all that can be wanted for all ordinary purposes by means of a scale much more nearly approaching a uniform price than the lighting one. For any purpose requiring a supply for 24 hours per day, it would seem to be unfair to make the same charge as for such intermittent use as is experienced in the case of hoists, so that an absolutely uniform rate might not be found satisfactory.

There has been an attempt to arrange a sliding scale of charging by means of meters which work on a different dial at certain hours, so that all units recorded on the second dial can be charged for at a higher price, these being the units consumed on the peak load; but up to the present no one has succeeded in producing a sufficiently cheap and satisfactory two-rate meter, so far as I am aware. Besides, if the system comes to be closely enquired into, I think it will be found that it does not fulfil the necessary requirements, and also that it is very difficult to decide as to how the arrangement should be worked during other months of the year than November, December, and January—that is to say, if the maximum price is to be charged between the hours of 4 and 6 p.m. during these months, during what hours is it to be charged in the other months of the year? It does not seem to me to take a grip of the correct principle, for it would result in charging a long-hour consumer the additional price during part of the 24 hours for the simple reason that somebody else wants to make use of the plant which is supplying him, and makes him pay extra for the other consumers' shortcomings. I must admit that I have not had occasion to think out this system of two-rate meters fully, but I simply mention it as one that should receive consideration in dealing with this subject. It may be that there are ways of getting over these difficulties.

You are aware that the Power Bills which have been recently passed by Parliament contain clauses to the effect that for the first 400 hours' use per quarter of the maximum demand quantity, the price shall not exceed 3d. per unit, and that for all further quantity the price shall not exceed 2d. per unit. This is very taking to the public eye, but where is the magic wand which enables the power companies to produce energy so wonderfully cheaply while we are unable to do so? The trick is very simple. There is no deception. The Bills contain other clauses which allow the companies to pick and choose their consumers and to make contracts with them in a way we cannot do. Of course, the companies say they do not want to supply light, and would not on any account wish to interfere with the corporations who already do so. They obviously wish to get the supply of power, and would willingly come into any municipality and supply it at low rates, leaving the corporations to supply light at much higher prices, which however, might still not pay. They are willing to supply light, too, under certain conditions if asked, and no doubt the price would be a favourable one; but what would the conditions be? They would be found to work out so that only long-hour demands, such as street-lighting or other all-night lighting, could be supplied under them. Is it not, therefore, a question whether it is right to allow these Bills to go through in this way? Surely the fact that they are tied down in price is against the general public interest. It would have been better, it seems to me, to have allowed them a higher maximum price, and to have bound them down closer to supply, on a sliding scale, the general wants of the community no matter whether for lighting or power. I would, in fact, put it to you that while, for power purposes only, the 3d. and 2d. tariff may be good enough, there should be in all these Bills a special scale for lighting, not perhaps with a maximum price per unit at all—for that may work unfairly to the company—but with a fixed charge per kilowatt per annum of, say, £8 or £9, or such other figure as may be found necessary, and 1d., or perhaps 2d., per unit for all current supplied. This is the principle first enunciated, I believe, by the late Dr. John Hopkinson. The principle of fixing a maximum price per unit, at any rate for lighting purposes, does not seem to me to be a desirable one at all, and it introduces complications in accounts which are entirely avoided by the other method, and at the same time there is a simplicity and justice about the £8 per kilowatt of maximum demand per annum which I have always found consumers of the longer-hour class to understand very readily. The fixed charge may be called a "plant rental," being, in fact, nothing but a rent for the plant which they use, and which must be kept for their use whether they want it all the year round or not. If you explain to a house factor that not paying the "plant rental" when you do not want to use the plant is like declining to pay a proportion of your house rent for such time as you may be absent at the coast or elsewhere in the summer, he takes in the situation at once.

The question of storage might under different circumstances affect the matter to some extent, but so far as I have been able to see, there is not much assistance to be got in that direction at present. I am indebted to Mr. Wilson for the gas load diagram now before you. It is taken from the Dawsholm Gas-

Digitized by Google

works, Glasgow, on a December day. The straight line across the sheet shows the "make" of gas. Storage in this case is an immense advantage, but we must not jump to the conclusion that storage would get us out of our difficulty as regards system of charge. Look at the whole diagram. It is so different from ours presumably because of the almost universal use of gas, owing to which a much better average load or load factor is obtained. It is probable, too, that our existence is of some assistance to the gas undertaking, as we have relieved it of so many of the short-hour and unprofitable consumers. It is not to be expected that our gas friends will take any great amount of pleasure in perusing our sliding-scale arrangements, because by means of them we shall probably obtain more long-hour consumers, and help to relieve them of some of the profitable as well as the unprofitable ones.

I ought, before concluding, to mention the name of Mr. Arthur Wright, our first president and the inventor of the maximum demand indicator, an instrument which has been of great assistance in the arrangement of sliding scales in the most equitable manner, by enabling us to charge only upon the actual maximum demand the consumer makes and not upon the size of his installation. I do not know whether I have succeeded in making the reasons for a sliding scale and against a uniform rate any clearer than they were, but the matter does seem to be of such importance that I hope some of you will take it up, and perhaps read a paper at our next convention, so that we may get a good discussion upon it.

Alderman BROWN, of Sunderland, rose to propose a vote of thanks to the president, and to request that the address might be printed in the *Proceedings* of the association. The need for a varied system of charging and the importance of the subject was shown by the fact that the Glasgow plant could generate 81 million units with its plant in one year, whereas only 6½ million units were required. He felt that the association were greatly indebted to Mr. Chamen for the clear and able way in which he had presented a most pressing subject.

Councillor J. GREEN HIRST, of Leeds, seconded the motion, which was carried by acclamation.

Mr. W. A. CHAMEN, in reply, said he hoped that the subject of his address would be taken up by someone in a paper at their next annual congress, so that a full discussion on the best system of charges might take place. He had only been able to briefly refer to the general principles involved, and hoped to give more details at such a discussion.

(To be continued.)

LEGAL INTELLIGENCE.

ST JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

In the High Court on Saturday, Mr. Justice Cozens-Hardy heard an application under the Memorandum of Association Act of 1890 to authorise the St. James's and Pall Mall Electric Light Company, Limited, to alter its memorandum by giving the company power to guarantee the repayment of the principal moneys and interest to secure the debentures of a company to be formed for similar objects to the applicants' company. It was explained that the St. James's Company required power to guarantee the payment of the capital of the Central Electric Supply Company. The banks had refused to advance any money on a guarantee for the interest alone. The amount required for the purchase of the land and the erection and equipment of the generating station was £350,000.

Eventually his Lordship granted the application, and confirmed the desired alteration.

BERRENBERG ELECTRIC LAMPS.

In the Chancery Division of the High Court, Mr. Justice Cozens-Hardy had the case of Glasier *v.* Berrenberg Electric Lamp Syndicate before him last Friday.

From the statement of counsel, it appeared that the plaintiffs are holders of 12 debentures of £100, which were issued by the defendant company in July last year. It was provided that the interest should become due on Dec. 31 last, but no interest was paid. Plaintiffs asked for the appointment of a receiver and manager, and defendant company not opposing, the application was granted.

SMOKE NUISANCE.

An action brought by Messrs. Hobson and Sugden, property owners, against the Buxton Urban District Council for allowing the chimney at the electricity works in Ashwood Dale to send forth black smoke in such quantities as to constitute a nuisance, came before the magistrates at Buxton on Saturday. It was stated for the prosecution that Buxton based its claims to patronage to a large extent on the purity of its air. The Council's solicitor contended that everything that was possible was being done to reduce the volume of smoke, and that the electrical engineer to the Council was of opinion that he had found a remedy for the nuisance. A fine of 10s. and costs was imposed

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers.

QUESTIONS.

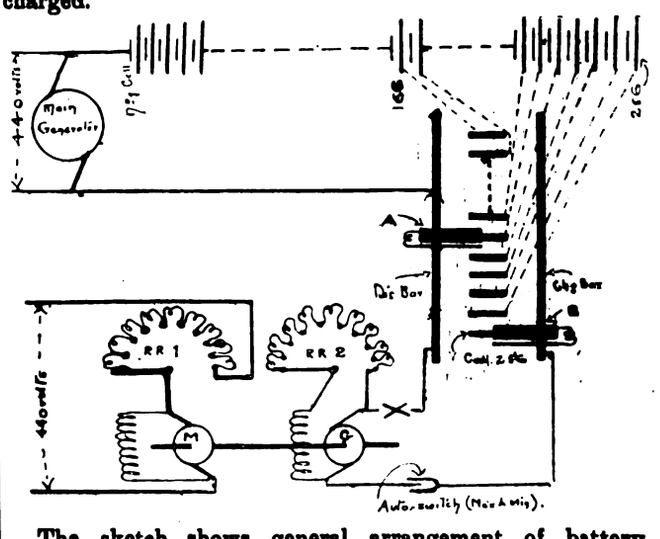
387. It is contemplated to transmit power to a direct-current lighting station a distance of five miles, by means of three-phase alternating current at 10,000 volts pressure. Which of the following systems of conversion would be best: (*a*) synchronous motor-generators; (*b*) asynchronous motor-generators; (*c*) transformers and rotary converters. Consider capital cost, over all efficiency, and practical ease and safety in working.—E. D. W.

388. In a large continuous-current central station it is believed there is a consumer using his current to earth. Which is the best way to detect and locate consumer?—A. F.

ANSWERS.

Question No. 381.—On a three-wire system, when the balancing set is shut down for repairs, and the remainder of the set is connected across the outers at 440 volts, and the motor-transformer is connected up for charging the regulation cells only, what would be the best method of charging up the main battery?

Best Answer to No. 381 (*awarded* 10*s.*).—The questioner does not state whether the battery is connected direct across the outers or as two distinct batteries each across outer and middle; also what type of regulating switch is employed, and should not motor-transformer read motor-generator? We will, however, assume that the battery is across the outers, and at 440 volts there are probably about 256 cells. Of these, say 166 comprise the main battery and 90 are connected up in threes as regulating cells on a 30-point regulating switch. We will also suppose that the motor-generator will give a voltage equal to about two-thirds of the regulators when fully charged.



The sketch shows general arrangement of battery regulating switch, connections of motor-generator, etc. In commencing charging operations, place right-hand switch, B, on contact on which discharge was stopped (say discharge was stopped on 256 cells); then work left-hand switch, A, up until the correct charging current is reached (the main generator voltage, of course, being kept constant). The motor-generator should now be started, and generator run up to voltage corresponding to the

Digitized by Google

number of cells between the two switch points, A and B, switched in circuit, and current brought up to working point by means of the regulating resistances, 1 and 2. The charging current would now be kept constant by working left-hand switch, A, and regulating resistances, 1 and 2. As end cells commence to gas, cut out by right-hand switch, B.—S. LEES.

Answer to No. 381 (*awarded* 5*s.*).—It is not quite clear from the question whether the balancer is a motor-balancer, or if it is used to drive the boosters for charging the top cells or steam balancer, and separate motor-generator for charging the top cells, with the remaining machines wound for 440 volts. Whichever it may be, if the balancer is shut down the balancing must be done with the cells. If the machine for charging the top cells is separate from the balancer no great difficulty should be experienced, especially if the balancer is not far out; and it may be mentioned that some stations depend entirely on the cells for balancing, charging the top cells from a motor-generator. All that is necessary to do, then, is to cut out cells till the correct charging current is reached on either side. If you are 10 amperes out of balance on the − side, to keep the balance the + side will have to have 10 more amperes than the − side, and so on. If the balancer consists of two separate steam dynamos, one of which is stopped for repairs, the other could be run on the heaviest loaded side so as not to give the battery too much balancing to do. Suppose that you were out of balance 80 amperes on the + side, and that the normal charging current of the battery was 60 amperes, if you gave the − 60 amperes the + would have to discharge 20 amperes to keep the balance, but if the balancing dynamo was run up on that side the cells could be charged as easily as if both machines of the balancer were running.—C. L. E. S.

Answer to No. 381 (*awarded* 5*s.*).—Owing to the minute particulars given with this question, it will perhaps be somewhat a difficult matter to describe fully what might be done to overcome the difficulty mentioned. It is therefore assumed in this answer that the large sets are coupled direct across the outers at 440 volts, and the balancing arranged to take place at the station end, there being no booster sets, but simply a motor-generator coupled to the regulating cells at the third wire—*i.e.*, the neutral. If the balancer is broken down it is evident that the work of balancing must be done by the battery, and should the load be a variable one, it will require the switchboard attendant's constant attention in order to keep as far as possible an even balance. Owing to the battery having to do the work of balancing, charging cannot be carried out regularly on either side, particularly if the mains are badly out of balance during the running hours, for it must follow that the side of the system having the heavier load cannot give much to the battery, but may require a little help from the battery, while the lightly-loaded side will be receiving a fairly large charging current.

From the above it may be seen that to attempt proper charging during the evening load would be a difficult matter, owing to the irregular charging and probable discharging of the battery. Of course, the charging may be done during the evening load by moving the battery regulators on the positive and negative sides low enough down to charge at the normal rate, but any appreciable amount of out of balance on the mains will upset the even charging of the cells, and too much of this is not caculated to benefit the battery. It appears, therefore, that the best plan to adopt in the case named would be to charge the battery in the daytime, or during the hours of light load. This can be done by starting up one of the sets coupled to the outers or outer 'bus bars, to which it is assumed the battery is connected, having its middle connected to the middle wire by means of the regulating cells. The machine having been put on the bars, the battery regulators should now be moved down so as to allow the normal charging current to enter the battery on each side; and since the load on the mains is small, little balancing will be required, and therefore an equal current may be got into each side. If the cells are gradually cut out on both sides, there will, of course, be a certain number left uncharged. These must be coupled in circuit with the motor-generator and charged independently, either during the time the main battery is being charged or after the charge, preferably the former, since the regulators must be brought higher again to maintain 'bus bar pressure after the charging ceases, so that a number of the cells previously left out of the main charging would be brought into circuit again without having received a full charge. The writer thinks that little difficulty should be experienced if the cells are charged as above suggested, and care is exercised to see that all parts of the battery—*i.e.*, regulators and main cells—are fully charged.—A. H.

Question No. 382.—What is a paralleling voltmeter? How is it connected when used on a three-wire system, and is it a necessary instrument?

Answer to No. 382 (*awarded* 7*s.* 6*d.*).—A paralleling voltmeter is an instrument used in central stations to facilitate the operation of throwing generators in parallel with machines already feeding the 'bus bars. These instruments have their zero in the middle of the scale, and when the voltage of the incoming machine is equal to that of the 'bus bars, the pointer of the instrument is a zero. Fig. 1 shows the connection for a three-wire system. If there are auto cut-outs, or single-pole switches in the dynamo's mains connected to the neutral wire, these must be closed first. Following up the dotted connections, it will be observed that one socket is connected to the 'bus + or −, and the other socket to the + or − of the dynamo's terminals. Let dynamos A and B be connected to the 'bus bars, and are maintaining a voltage of, say, 250 volts between the neutral and the outers, and it is necessary to switch dynamo C into parallel. If a voltmeter having its zero in the middle of the scale be connected to points 1 and 2 (which may represent the contacts of a multiple switch), it is obvious that if contact 1 be connected to the 'bus and No. 2 to the similar

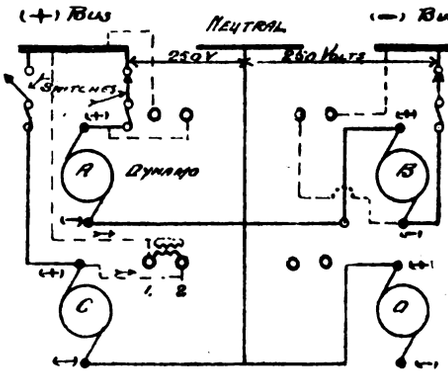


FIG. 1.

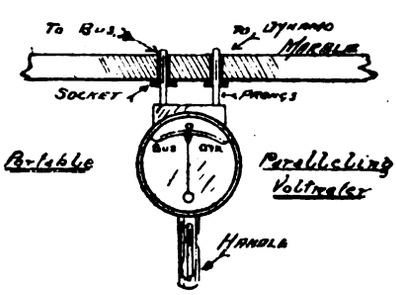

FIG. 2.

pole of the dynamo, no flow of current can take place through the instrument when the voltage of the incoming machine is equal to that across the 'bus and the neutral, the pointer is at zero. If the voltage of the incoming machine is higher than that of the 'bus bars, the pointer of the instrument will be deflected to one side of zero, or if the voltage of the 'bus is higher than the machine volts, the pointer will be deflected on to the other side of zero. It is usual, however, to switch in the incoming machine at two or three volts above the 'bus bars, so as to allow for the drop of potential which takes place in the machine when it is thrown in. Messrs. Kelvin and James White, Limited, have introduced a most convenient portable type of paralleling

Digitized by Google

voltmeter, which are arranged as follows: on each of the dynamo panels are fixed two gunmetal sockets at about 3in. apart, and when a machine is required to be run up for switching in parallel, the instrument, which has two metal prongs, is pushed into these sockets, as in Fig. 2. These instruments are extremely handy, and can be used for paralleling any number of machines.

In answer to the latter part of the question, a paralleling voltmeter is not a necessary accessory for the above purpose; ordinary voltmeters can serve the same purpose. On the other hand, zero paralleling voltmeters save a lot of trouble, especially if the ordinary type of voltmeters installed on the switchboard are not reading accurately together.—R. H. FULTON.

Answer to No. 382 (*awarded* 7*s.* 6*d.*).—A paralleling voltmeter is a most useful and handy little instrument. It is used for ascertaining when the voltage of any machine corresponds with that of the 'bus bars on to which it is to be paralleled, therefore giving the correct time to close the main switch without causing the slightest flicker on the

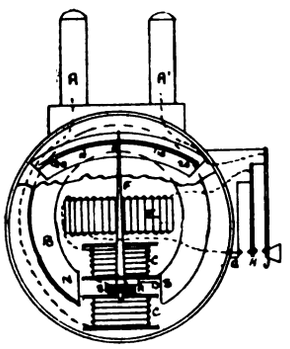

FIG. 1.

lamps. Fig. 1 shows diagram of paralleling voltmeter and connections. A A' are the plugs which fit suitable plug holes in the main dynamo board. B is the permanent magnet which retains the pivoted permanent magnet, D, in zero or mid position when no current is flowing in the coils. The coils, C C, are both wound to act together, and

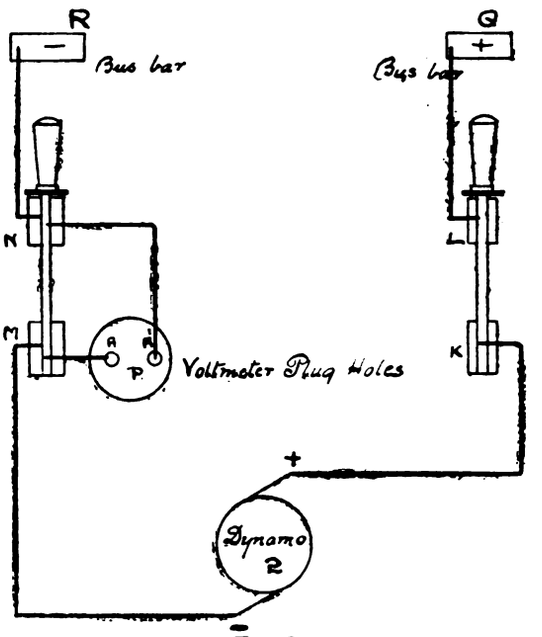

FIG. 2.

tend to move the magnet, D, and, therefore, pointer, F, from zero to either right or left, depending on the direction of the current. E is a resistance, and G H J the switch key and contacts. Fig. 2 shows the connections necessary for the paralleling voltmeter fitting on the main board, each machine being supplied with its own fitting. The contacts, A A', are connected, one to the machine side, and the other to the 'bus-bar side of the main switch. It is immaterial whether the fitting is connected to the + or the − switch, but the usual practice is as shown on sketch. Suppose dynamo 2 is to be paralleled on to the main 'bus bars, Q and R. The engine is started up and the + switch is then closed. The paralleling voltmeter is then plugged into holes, A A', on the board. As the engine is being run up to speed, the key, J, on the voltmeter is pressed on to contact H, and on the first trial there is usually a violent oscillation to either right or left due to the widely different potentials at the contacts N M. As the engine more nearly approaches the proper speed, the difference of potential will grow less and less so that the pointer hardly moves. The key, J, is then pressed further down to the contact G, thereby cutting out the largest portion of the resistance, E. The final adjustment of speed is then made, and when the voltmeter registers zero the main switch is closed. If the key, J, had been pressed down to G, on starting up there would be great risk of burning up the coils, C C, due to the wide difference of potential, but as the voltage of the machine approaches that of the 'bus bar, the greater portion of the resistance, E, may be cut out. The voltmeter is connected up exactly the same for a three-wire as a two-wire system. The great advantage of the paralleling voltmeter is that the man who closes the switch can see the voltmeter, and does not depend on another man to tell him or signal to him when to close it; the usual result in the latter case is a flicker on the lamps. The cost for connections is very slight indeed, and in most cases it would be necessary to have another voltmeter on the board if the paralleling voltmeter was dispensed with. It is not an absolutely necessary instrument, but its advantages are so great and apparent that it is folly to be without one. The ammeter shunt, fuses, etc., are not shown in the dynamo circuit (Fig. 2), as they are not necessary for the question.—H. B.

Answer to No. 382 (*awarded* 5*s.*).—A paralleling voltmeter is essentially a polarised voltmeter having its zero position in the middle of the scale—*i.e.*, there are practically two scales, one on each side of the zero position and reading in opposite directions, so that the person manipulating can ascertain at a glance by how much and in what manner the potential difference of the dynamo differs from that of the 'bus bars to which it is to be coupled. The voltmeter is usually connected between the terminals of one of the dynamo switches, and a light fuse in the other switch to complete the circuit through the switchboard 'bus bar.

A convenient form of voltmeter is that depicted in Fig. 1, and is made by Messrs. Kelvin and White, of

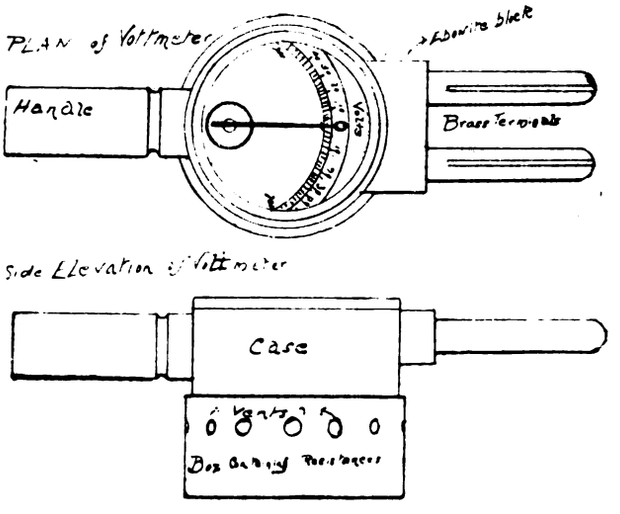

FIG. 1.

Glasgow. This voltmeter is only placed in circuit when the dynamo is to be paralleled, and is removed when the dynamo has been switched on to the bars. The sockets to receive the terminals of the voltmeter are fixed in some convenient position on the switchboard, preferably near to the dynamo switch, and the necessary connections are shown in Fig. 2. In cases where the dynamo has only a single-pole switch it is necessary to have a fuse in one of the socket connections in order to protect the voltmeter from possible harm.

On some switchboards two voltmeters are used, one

Digitized by Google

across the 'bus bars, the other across the dynamo terminals; and these voltmeters are often electrostatic voltmeters that indicate in the same manner in whatever direction

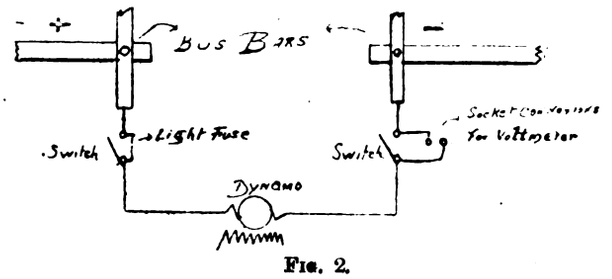

Fig. 2.

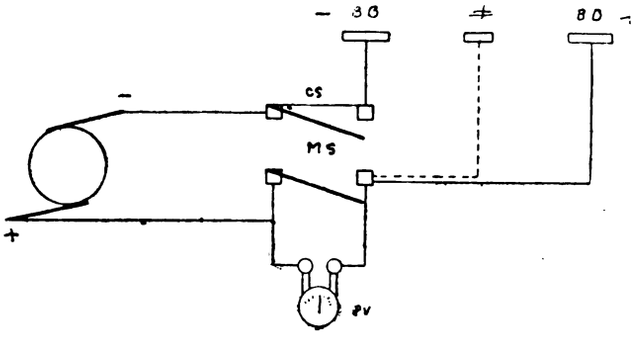
the voltage is applied to the terminals. The ordinary type of voltmeter does not indicate on the wrong side of zero, because they are not made to, and do not, therefore, indicate a reversed current. In the case of the electrostatic voltmeter it is positively dangerous, for who is to know when the magnetism of the dynamo is reversed—a state of affairs which, fortunately, is not of very frequent occurrence. With the ordinary type of voltmeter, time may be wasted endeavouring to excite the dynamos when it may possibly be exciting in the wrong direction, or, indeed, the voltmeter connections may have been reversed. I, therefore, consider it a matter of safety as well as necessity that a proper paralleling voltmeter should be used for paralleling dynamos on all switchboards.—C. H.

Answer to No. 382 (*awarded* 5*s.*).—A paralleling voltmeter is used for ascertaining the exact moment for switching on a dynamo in parallel with another, or others already working. It usually consists of a portable instrument with coils of high resistance, and spring balance to keep needle at zero when no current is passing. It has plug terminals, so that it can be connected up to any machine by suitable contact sockets arranged close to the main dynamo switches, so that the attendant can see and use same in switching on machine. It is calibrated with zero in centre of dial, and reads to either way to a voltage suitable for station. There is a double-contact key attached. On making first contact circuit is closed, and either way will read, say, 200 volts, each division being 10. On making second contact, either way will read, say, 20, and each division will equal one. The reason of this will be explained later. It is connected up as follows. I think the diagram will explain itself, and



shows one machine across the outers in a three-wire system. If two machines in series were used it could either be connected in series with them if put on together, or else if machines were being put on one side at a time it could be connected as shown by dotted line to neutral, and whichever side, as case may be. The reference letters on the diagram are: B B, 'bus bars; M S, main dynamo double-pole switch; P V, paralleling voltmeter; C S, light spring contact strip used to complete voltmeter circuit.

It will be seen from sketch that there is (when voltmeter key is closed) a complete circuit from one 'bus bar through voltmeter to machine, from machine to main switch, through contact strip to other bar. So the machine is practically "on," but the voltmeter being of such high resistance, little or *no* current passes. Therefore, when machine volts = bar volts, the counter E.M.F.'s tend to keep the needle at zero. If, however, either machine volts are higher or lower than bar volts, the needle will swing to left or right as case may be. The method of using is as follows: As soon as oncoming machine starts generating, make first contact; needle will swing to one side. As machine volts rise, it will come up gradually to zero. When about 20 volts from zero, make second contact, and needle will go back and come up rapidly again to zero, each division reading one volt, therefore giving a larger scope for putting "on" at the exact voltage, which should be about one volt above bar volts. As soon as needle is up, switch on, and there should be practically no "bobbing" of the lights or volts. No; it is not an absolutely necessary instrument, although a far better way of working than any other method, such as watching machine voltmeter and 'bus-bar voltmeter and switching on when they show a like voltage, as they may read a little out, and so cause "bobbing."—M. H. V.

Lecturer and Demonstrator, Hull Municipal Technical School, £150 per annum. Details in our advertisement columns.

Manager, copper tube works of English Electro-Metallurgical Company, Limited, Leeds. Details in our advertisement columns.

Assistant Superintendent of Mains, Edinburgh Corporation, about £100 per annum, July 1. Details in our advertisement columns.

Chief Clerk in the consumers' department, London electricity supply company, £120 to £150. Details in our advertisement columns.

Electrical Engineers, Dewsbury, £250 per annum, to be increased at the end of 12 months to £300, July 4; tramways, Council of the city of Wellington, New Zealand, July 20. Details in our advertisement columns.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Brighton.—The Guardians require tenders for the wiring of the workhouse.

Taunton.—The Corporation invite tenders for free wiring. Tenders by July 1.

Stepney.—The Borough Council invite tenders for supply of arc lamp carbons for the year ending June 30, 1902. Tenders by June 26.

Manchester.—The Tramways Committee invite tenders for the supply of tramway rail bonds. Tenders by July 1. Details in our advertisement columns.

Dudley.—The Electric Light and Tramways Committee invite tenders for the supply and erection of a steam engine and dynamo. Tenders by July 6. Details in our advertisement columns.

Poplar.—The Electricity Committee invite tenders for the supply of condensing plant, boiler feed pump, and steam and water piping, etc. Tenders by July 1. Details in our advertisement columns.

Nelson.—The Electricity and Tramways Committee invite tenders for supply, etc., at their electricity works of a travelling crane. Particulars may be obtained from Mr. W. Alan Fraser. Tenders by 25th inst.

Whitehaven.—The Water and Lighting Committee invite tenders for the purchase of about 20 tons of second-hand rubber-covered cables. Tenders by June 24. Particulars in our advertisement columns.

Leigh.—The Tramways and Electricity Committee invite tenders for the supply of electricity meters for a period of 12 months ending June 30, 1902. Tenders by June 22. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for electric motors (enclosed type), of 4½ h.p., 7 h.p., and 10 h.p., for a period of 12 months commencing Nov. 1, 1901. Tenders by July 4. Details in our advertisement columns.

Poplar.—The Electricity Committee invite tenders for the supply of multiple-core lead-covered feeder and network cable and accessories for mains extensions. Tenders by July 2. Particulars in our advertisement columns.

Digitized by Google

West Ham.—The Council invite tenders for two 500-kw. continuous-current tramway generators, coupled direct to three 850-i.h.p. steam engines, and 11 water-tube boilers. Tenders by June 25. Details in our advertisement columns.

Madrid.—The Public Works Department of the Department of Agriculture, Madrid, invite tenders for the construction and working for 60 years of an electric tramway from Santiario de la Yedra to Balza. Tenders by July 26. Particulars at that office.

Nelson.—The Corporation invite tenders for steam engine and dynamo, balancer, two 30ft. by 8ft. Lancashire boilers, feed pumps, economiser, etc., condenser and steam pipes, cables, and switchboards. Tenders by July 1. Details in our advertisement columns.

Pontypridd.—Tenders are invited by the Guardians for the lighting of the union workhouse, infirmary, and other buildings in connection therewith by electricity. Tenders must be received by Mr. William Spickett, clerk, Union Offices, Pontypridd, on or before July 23.

Brighton.—The Town Council invite tenders for the supply and fixing of all the wiring and fittings necessary for the electric lighting of the new floral hall of the market. Specifications, etc., may be obtained at the office of the borough engineer and surveyor, Mr. Francis J. C. May, M.I.C.E. Tenders by July 26.

Manchester.—Tenders are invited by the Electricity Committee for the supply of the following stores during 12 months ending June 30, 1902—viz.: brass and iron castings, coal slack, cement, cotton waste, flags, incandescent lamps, meters, oils, timber, etc. Particulars, etc., may be obtained from Mr. F. E. Hughes, secretary, Electricity Department. Tenders by July 2.

Birkenhead.—Tenders are invited by the Corporation for the construction, supply, and delivery of 15 electric tramcar bodies, complete electrical equipments for 15 cars, and trucks and trolleys complete for 15 cars. Specifications, etc., may be obtained on application to Mr. Arthur R. Fearnley, tramways manager, Sessions House, Brandon-street, Birkenhead. Tenders by July 16.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

Epsom.—The Urban District Council invite tenders for supply of meters (direct-current) and cut-outs. Specifications, etc., can be obtained from Mr. E. G. Wilson, clerk, High-street, Epsom, on deposit of £2. 2s. for each specification, returnable on receipt of a bona fide tender. Specifications may be seen at, but not obtained from, the offices of Mr. W. C. C. Hawtayne, 9, Queen-street-place, London, E.C. Tenders by 12 noon on 22nd inst.

London, N.E.—Tenders are invited for the erection and construction of mechanical coaling apparatus for the municipal electricity works, for the Electric Lighting Committee of the metropolitan borough of Hackney. Specification, etc., may be obtained at the offices of Mr. Robert Hammond, M.I.C.E., consulting engineer to the Corporation, 64, Victoria-street, Westminster, London, S.W., on payment of £1. 1s. Tenders by 4 p.m. on July 4.

London, S.E.—The Borough Council invite tenders for the supply of electricity meters, demand indicators, and main fuses. Specifications, etc., can be obtained at the Town Hall, Spa-road, Bermondsey, on payment of a fee of £3. 3s., which will be returned on receipt of a bona fide tender. The specification may also be inspected (but not obtained) at the offices of the engineers, Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by noon on July 1.

Mansfield.—The Corporation invite tenders for the supply and erection of—boiler-house plant: three Lancashire boilers, mechanical stokers, steam pumps, economiser, and motor; engine-house plant: three 200-kw. high-speed steam generators, motor transformer, balancing motor transformer, and accessories; Korting condensers and electric pumps, switchboard and instruments, accumulators, overhead travelling crane, electricity supply mains; public lighting: arc lamps, posts, and accessories; meters, and workshop equipment. Tenders by July 12. Details in our advertisement columns.

Erith.—The Urban District Council invite tenders for the supply and erection of two Lancashire boilers, with fittings, economiser, feed pumps, etc.; pipework, etc., in engine and boiler house; surface-condensing plant, three steam alternators (vertical enclosed high-speed engines direct coupled to three-phase alternators), main switchboard and connections, 10-ton engine-room travelling crane, transformers, sub-stations, and equipment, underground mains, conduits, roadwork for private and public lighting, arc lamps (open type), posts, and station lighting. Tenders by June 24. Details in our advertisement columns.

Cleckheaton.—The Urban District Council invite tenders for the supply and erection of the following plant: (Section C) engines, dynamos. Tenderers must tender for the whole of the section, and not for part of it. Specifications, etc., may be inspected at the offices of Messrs. Gibbings and Baker, Piccadilly-mansions, 17, Shaftesbury-avenue, London, W., and Old Bank-chambers, Cheapside, Bradford, on and after 8th inst., and may be obtained on application to the Clerk of the Council, Town Hall, Cleckheaton, on payment of the sum of £2. 2s., which sum will be refunded on return of specification with bona fide tender. Tenders by 22nd inst.

Hurst (Lancs.).—The Urban District Council invite tenders for the construction of the permanent way of the tramways, including the supply of labour and material (except granite setts, which will be provided by the Council) for the concrete foundations, and other contingent work; also the fixing of grooved steel girder tramway rails, points and crossings, fishplates, tiebars, bolts and nuts, together with the material and labour required in the electric copper bonding of the rails, points, and crossings, etc., and all other work connected therewith. Specifications, etc., may be obtained at the office of Mr. Edward Garside, A.M.I.C.E., Town Hall-chambers, Ashton-under-Lyne. Tenders by 12 noon on 28th inst.

RESULTS OF TENDERS:

Keynsham.—The Parish Council have accepted the tender of the Electric Lighting Company, at £188. 10s., for lighting the parish.

Dundee.—The Corporation have accepted the tender of the International Electric Company, of Liege, at £4,283, for a three-phase direct-coupled engine and dynamo, according to specification.

Oldham.—The Electrical Company, Limited, Charing Cross-road, W.C., have received an order from Messrs. Asa Lees and Co., Oldham, for one three-phase generator, 350 kw., and the necessary motors for driving their shops electrically.

Fulham.—The Borough Council of Fulham have accepted the tender of the General Electric Company (1900), Limited, for the supply of Robertson lamps, arc lamps and accessories, fuse wire, tape, etc., as required until March 31, 1902.

Lowestoft.—The tender of the Wheeler Condensing and Engineering Company for plant to condense for 130-h.p. and 230-h.p. engines combined, or to deal with either separately, or the 330-h.p. engine now on order, is recommended for acceptance.

Cape Colony.—The Allgemeine Elektricitäts-Gesellschaft, Berlin, have received the contract from the Cape Town Government for the Table Bay Harbour plant, consisting of three 250-kw. direct-current dynamos, coupled direct to Belliss and Morcom engines, Davey-Paxman and Co.'s boilers and cranes, from three tons up to eight tons carrying capacity, and 11 capstans. The mechanical part of the cranes is supplied by Messrs. Stothert and Pitt, Limited, Bath.

Dublin.—The Lighting Committee have recommended to the Council the acceptance of the following tenders: Specification 4: Section E (condensers), Alley and Maclellan, £3,030; Section F (pipework), Babcock and Wilcox, £4,805; Section G (feed pumps), D. Stewart and Co., £395; Section H (superheaters), Part 1, J. Musgrave and Sons £832, Part 2, Babcock and Wilcox £705; Section J (coaling plant), Graham, Morton, and Co., Limited, £5,475; Section K (overhead crane), Carrick and Ritchie, £670; Section L (workshop plant), Easterbrook, Allcard, and Co., £795. Specification 5: Section M (main switchboards), General Electric Company, £3,814; Section N (sub-station switch gear), Brush Electric Engineering Company, £5,800; Section O (transformers), British Westinghouse Electric Company, £6,320; Section P (arc lamps), Verity's, Limited, £6,198; Section Q (arc lamp pillars), Verity's, Limited, £6,042. Specification 6: Section R (motor and motor-generators), Witting Bros., £3,970; Section S (accumulators), Electric Power Storage Syndicate, Limited, £751; Section T (meters), British Westinghouse Electric and Manufacturing Company, £4,670; Section U (works wiring), W. Coates and Sons, £967. Specification 7: (the building of the 19 small sub-stations around the city), J. and W. Stewart, Belfast, at £275 each, or a total, if all should be required unaltered, of £5,225. The total of the tenders recommended amount to £60,566, the original estimate of Mr. Hammond for these portions of the work being £62,551.

BUSINESS NOTES.

TRACTION.

Llandudno.—The District Council have approved further plans in connection with the proposed Great Orme tramway.

Darlington.—The General Purposes Committee have approved the form of agreement for the purchase of the tramways.

Hill of Howth.—The electric tramway between Sutton Station and the summit of Howth Head is now open to the public.

West Cumberland Tramways.—In the House of Commons the West Cumberland Electric Tramways Bill was read a third time.

Hindley.—Mr. W. J. Lomax, C.E., of Bolton, has been retained to value the tramways in Hindley on behalf of the District Council.

Lancaster.—The Corporation have decided to proceed with two sections of their electric tramway scheme—viz., to the Lancaster Park and to Scotforth.

Easdale.—The Parish Council have unanimously resolved "to do all in their power" to forward the proposal to construct a light railway from Oban to Easdale.

Ayr.—The Town Council have authorised the surveyor to purchase an additional quantity of 20 tons of tramrails, with corresponding quantity of fishplates, etc.

Southend.—It is expected that the new electric tramway system will be formally opened within a few days, the preliminary trials having proved quite satisfactory.

Digitized by Google

Greenwich.—The Borough Council have decided to dissent from the proposal of the light railway promoters to apply for an order authorising a light railway from Woolwich to Eltham.

Norden.—The ceremony of "laying" the first rail of the new electric tramways between Rochdale and Norden was performed at the end of last week by the chairman of the Tramways Committee.

Molesey.—The District Council have agreed to withdraw their opposition to the London United Tramway Company's Bill now before Parliament on terms, one condition being that wood paving shall be laid.

Ramsbottom.—The District Council have signified their approval of the arrangements come to between the Tramways Committee and the promoters of the two schemes of light railways in the district.

Motor Vehicles and Horses.—A meeting of the Church Society for the Promotion of Kindness to Animals has passed a resolution urging that the more general adoption of motors would alleviate much animal suffering.

Hornsey.—A public meeting of owners and residents at Muswell-hill has unanimously resolved to oppose the application of the Middlesex County Council for an order to construct light railways in the district.

British Electric Traction Co.—The directors of this Company recommend a dividend at the rate of 12 per cent. per annum for the half-year ended March 31, making, with the interim dividend, a total distribution of 9 per cent. for the year.

Tower Wagons.—Messrs. J. H. Heathman and Co. have just issued another price list of their telescopic tower wagons, which are now being extensively used for a variety of purposes, including the erection of electric tramway overhead wires, etc.

Islington.—The Borough Council, having arranged satisfactory clauses with the promoters of the Islington and Euston Railway and of the Charing Cross, Euston, and Hampstead Railway (No. 2) schemes, have withdrawn their opposition to the Bills.

Stoke Newington.—With reference to the proposed North-East London "tube," the Highways Committee are of opinion that the line will afford great and necessary facilities to the inhabitants of the borough desirous of travelling to the City or West-end.

Islington.—The City and South London Railway Company, in reply to a letter from the Borough Council requesting a station to be placed at Highbury-corner, state that, in view of the cost involved, the directors do not see their way to accede to the request.

Blackburn.—During the month of April the Corporation cars ran 47,500 miles, carried 486,869 passengers, the total receipts being £2,381. 3s. 7d. On the Darwen section the figures were: miles run, 15,099; passengers carried, 186,936; and receipts, £790. 0s. 11d.

Surbiton.—In the agreement between the District Council and the London United Tramways Company, the company have agreed to widen the Ewell and Ditton roads so that a space of not less than 9ft. 6in. should be left between the kerb and the nearest rail of the tramway.

Middlesex.—The Highways Committee of the County Council have decided to grant a motorcar for their chief surveyor of main roads, believing he can cover twice as much ground as he could with horses, and obtain a more thorough appreciation of any defects in the roads.

Manchester-Liverpool Electric Express Bill.—This Bill was before the Examiners for the Investigation of Standing Order Proofs at the House of Commons on Tuesday, it having passed the Lords, and was found to have complied with the Standing Orders of Parliament.

Oldham.—The Park-road, Glodwick-road, and Lees-road sections of the Corporation tramways were formally declared open on Saturday. These lines form part of a scheme for the construction of 25 miles of electric tramways within the borough, and the portions now open are 2¾ miles in length.

Wembley.—In connection with the proposal of the Middlesex County Council to obtain powers to construct light railways in the district, the Urban District Council have resolved, subject to satisfactory arrangements being made as to road widening, not to oppose the construction of a tram or light railway line between Stonebridge and the Swan Inn.

Ashton.—The contract for the rails for the proposed Corporation electric tramways has been placed with Messrs. Dick, Kerr, and Co., Limited. Tenders are to be invited for the necessary points and crossings. The Corporation have accepted the offer of the Hurst District Council to lease to them the proposed tramway lines for Hurst for 10 years upon terms.

Wolverhampton.—Progress continues to be made with the work of laying the electric tramlines in New Hampton-road and the Whitmore Reans. Further advances in all departments may be anticipated, and as the work of putting in the connecting cables gets on, a start will be made with the laying of the supply cable and its adjuncts down the edge of the footpath.

St. Paul's Cathedral and Tube Vibration.—Mr. Wm. Emerson, the president of the Royal Institute of British Architects, writing on the subject of the proposal to carry the Piccadilly and City Railway close to St. Paul's Cathedral says, it is not the particular violence of the vibrations that might be set up, but the constant quantity that would probably eventually affect the structure.

Loughborough.—The Town Council have sealed an agreement with the Loughborough and District Electric Traction Company, Limited, with regard to the contribution by the Corporation to the company of the sum of £10,000 towards the proposed railway in the district, and also a supplemental agreement with the same company containing clauses for the protection of the Corporation.

Whitehaven.—The Parliamentary Committee reported at the last meeting of the Town Council that they had obtained a clause in the West Cumberland Electric Tramways Bill to the effect that if the tramways from Cleator Moor to the boundary of Workington parish were not substantially commenced within two years from the passing of the Act the powers for making them should cease.

Doncaster.—The Tramways Committee has accepted tenders for rails for the proposed electric tramways. It has been decided in regard to the route through the wool market to take part of the market, and one of the bays will be used as a car-shed. It has also been decided to make a double line from the clock corner in High street to the Race Common at an additional cost of £5,000.

South Shields.—At the last meeting of the Town Council it was proposed that the Corporation obtain powers in the next session of Parliament for laying down and working a complete system of electric tramways in the borough. It was pointed out that the Tramways Committee had the matter under consideration, and an amendment that the question be referred back to them was carried.

Newcastle.—At a meeting of the Tramways Committee an interesting report was submitted, containing the recommendations of the General Purposes Committee, relative to sections and stopping places, in regard to the new tramways. It is proposed to have halfpenny fares for each section. The sections will be 1,277 yards in length, or an average of little less than three-quarters of a mile.

Swiss Electric Railway.—The Limmat Valley Electric Road Railway, which is eight miles in length and connects a number of large villages with the town of Zürich, Switzerland, was opened for traffic in April last. The line has been constructed under the direction of Dr. Du Riche Preller, M.I.E.E., as managing director and chief engineer, the contractors being Brown, Boveri, and Co., Limited, of Baden.

Glasgow.—A breakdown of the overhead wires in connection with the Corporation electric tramway system occurred on Saturday last in the Sandyford district of the city. A number of the cars were brought to a stop in consequence. There were no passengers on the car at the time of the breakdown, and the accident happening at night, there was little traffic on the street and very few people were about.

Damages for Personal Injuries.—Some months ago Mr. Fitzgerald obtained a verdict in the court of first instance in Dublin against the Dublin United Tramways Company for £1,000 damages for personal injuries, he having been pitched from his trap owing to his horse slipping and falling on the tram tracks. The Court of Appeal have now upheld the verdict, on the ground that the company were negligent in failing to keep the track well sanded.

Bath.—No further delay is anticipated with regard to the introduction of electric tramways into Bath. The Corporation and the promoters have joined hands, and the Light Railway Commissioners have issued the necessary order. Discussion took place at the Council meeting on Tuesday upon the advantages of the conduit as compared with the overhead system, but the chairman of the committee declared that the former was impossible in Bath.

Private Bills.—In the House of Lords the following Bills have been read a second time: Derbyshire and Nottinghamshire Electric Power, Tottenham and Hampstead Junction Railway, and Shannon Water and Electric Power. In the Commons the following Bills have been read a second time: Birmingham (City) Tramways, Wigan Corporation Tramways, and Metropolitan District Railway; and the following a third time: Notting Hill Electric Lighting, and Metropolitan Electric Supply.

Finchley and Hendon Tramways.—The Select Committee of the House of Lords presided over by Lord Pirbright on Tuesday concluded the consideration of the Bill under which powers are sought to construct tramways from Golder's Green to Hendon and Finchley in conjunction with the Charing Cross, Euston, and Hampstead Tubular Railway. The idea is to connect these outside districts with the heart of London by a continuous and expeditious service. The preamble of the Bill was found to be proved.

Liverpool.—A return for the fortnight ended June 8, submitted by the general manager of the Corporation tramways, shows that the total mileage run was 428 012, being an increase of 82,455 on that of the same period last year. The number of passengers carried during this fortnight was 4,221,716 being an increase of 893,866 over that for the corresponding period last year, and the receipts for the fortnight amounted to £19 748 19s. 5d., being an increase of £2,407. 14s. 9d. over that of the corresponding period last year.

Bradford.—The receipts on the various lines of city tramways during the week ended June 16 were: Bolton, £161, or 12 09d. per mile run; Horton £505, or 15 72d. per mile; Lidget Green, £139, 12·12d. per mile; Whetley Hill, £206, 13·31d. per mile; Thornton, £67 6 22d. per mile; and Stanningley, £63 9·08d. per mile. The receipts per mile run for the various lines from or subsequent to April 1 last have been: Bolton, 12·58d.; Horton, 12·24d.; Lidget Green, 11·97d.; Whetley Hill, 13·34d.; Thornton, 6·92d.; and Stanningley, 9 2d.

Stirling.—At the Town Council's meeting on Tuesday a letter was read from the Stirling and Bridge of Allan Tramways Company in regard to the negotiations for the transference of the line to the

Digitized by Google

British Electric Traction Company, which have been broken off in consequence of the Town Council, in order to safeguard their interests, giving notice of their intention to purchase the part of the line within the burgh. A remit was made to the Lighting Committee to ascertain the value of the undertaking within the burgh, with powers to open negotiations with a new electric company.

Southampton.—The question of the new electric tramways was raised at the last meeting of the Town Council, when it was stated that the Corporation were now running an enormous mileage, and the committee had come to the conclusion that the cars were equipped with the wrong kind of wheels, and that those at present in use were too soft. The wheels at present in use were American, and they found they were constantly getting flats and chips. The committee were going to try the experiment of using steel-tyred wheels, and hoped to get better results. The new wheels would be of English make, and entail much heavier expense.

Burnley Tramways.—At the final meeting of the shareholders of the Burnley and District Tramway Company, now in the hands of the Corporation, it was explained that after paying the shareholders 21s. in the pound with interest, there would be left a balance of about £2,500 to meet any contingent claims. The directors had made the manager, Mr. H. Mozley, a grant of £200 for extra work, and they had all reason to congratulate themselves at the satisfactory winding-up of the company. The report was unanimously adopted. It was stated that the money would be paid to the shareholders in one lump sum, probably in August.

Manx Tramways.—A circular issued to the shareholders in the Isle of Man Tramways and the Electric Power Company, Limited, impresses the importance of the purchase by the shareholders of the company's concern from the liquidator, and suggests that the shareholders should subscribe the capital, which, added to £175,000 debentures which could probably be raised, would be sufficient to purchase the undertaking and to pay the preliminary expenses. Shareholders are asked to subscribe 5s. per £100 of holding. It is stated that there is no probability of the shareholders receiving anything from the realisation of the company's assets.

Aberdeen.—Very satisfactory progress has lately been made with the construction of the electric tramway route to the bathing station, and the permanent way and overhead equipment of the part of the track from Castle-street to the east end of Constitution-street being now completed, a trial run has been made with one of the new cars, 12 of which have been obtained for this route. It is expected that a trial run will be made on the remaining portion of the route to the beach—the third-rail section, across the Links—in a few days, and after the sanction of the Board of Trade has been received the ordinary traffic on the route will be commenced.

Harrow.—It is reported that Dr. Wood, headmaster of Harrow School, has called a meeting of townspeople to protest against the Middlesex County Council's scheme for a line of electric trams to pass down the Harrow-road and round in a semi-circle to the Edgware-road, along which it would return to the starting point. The trams would pass over Harrow Hill and between many of the schoolhouses and buildings. The plans show that it is proposed to lower the crest of the hill in a manner that would expose the foundations of the school, chapel, and speech-room, and the scheme is meeting with the strongest opposition from the school authorities, as well as from many of the townspeople.

Warrington.—Colonel von Donop has held a Board of Trade enquiry into the application of the Corporation for powers to borrow £66,000 for the purpose of laying tramlines from Sankey Bridges to Latchford Swingbridge, and a branch line from Warrington Bridge to the swingbridge, Stockton Heath. It is proposed to have the overhead system, with eight cars for the main line, and an additional three cars for the branch line. There was considerable opposition to the application on the ground that the tramways would not pay. Mr. Preece, who was the chief witness, said it would require 10½d. per mile to make it pay, and, judging by the number of passengers by the 'buses, there was a probable margin of profit.

Sunderland.—At the monthly Town Council meeting the Tramways Committee reported that notice had been received from the British Electric Traction Company of intention to apply for an order authorising the construction of light railways from Sunderland to South Shields, and, by instruction of the committee, the town clerk had given notice of dissent from the laying by the company of any portion of their proposed tramways in Whitburn-road within the borough boundary. The Villette-road extension at Hendon of the Corporation tramways is now ready for the Board of Trade inspection. The traffic receipts for the fortnight ended June 5 amount to £2,500, an increase of £1,800 on the corresponding period of last year, when horse traction was in vogue.

Wallsend.—At the monthly meeting of the District Council a lengthy report was read as to the Tyneside Tramways Bill. It stated that a formal undertaking had been given that if the Bill passed the electric trams would not be run over the Willington Gut Bridge until it had been widened as agreed with the County Council, the width to be 40ft. 9in. The promoters agreed to pay the cost of the Council, and they had struck out the provision relating to the minimum charge of 2d., the maximum fare being 1d. per mile. A clause had been inserted to run a proper and sufficient service of cars for artisans, mechanics, and daily labourers each way, the charge for such trams not to exceed ½d. per mile. An undertaking with regard to the compulsory purchase clause as required by the Council had also been given.

Halifax.—The proposal of the Corporation to secure the vacant land in Commercial-street, with a view to making a tramway centre for the city, has created much interest and some adverse criticisms among the citizens. The purchase of the land will amount to £68,000, and its development, including the making of new streets, etc., would, it is thought, bring the cost up to close on £90,000. It is estimated, however, that £40,000 would be realised by the sale of surplus land. The Corporation, it is said, have reached the limit of borrowing powers for improvement purposes generally sanctioned by the Local Government Board, having regard to the ratable value to which Halifax can lay claim. A parliamentary Bill therefore would be necessary, and one thing essential in the promotion of a parliamentary Bill is the assent of a meeting of ratepayers.

Scarborough.—The town clerk has been instructed to write to various tramway experts and enquire their terms as advisers to the Corporation in connection with the proposed electric tramways for the town. The borough engineer will be instructed to prepare plans, when the expert is engaged, to be laid before Parliament. It is expected that the requisite documents will be deposited in time to enable the Bill to come before the next session of Parliament. The town clerk has drawn up a report relative to the procedure which might be adopted by the Corporation in dealing with the question of the tramways. Having considered the advisability of promoting a Bill in Parliament or obtaining a provisional order, it has been decided to adopt the former course. The feeling is that when the Bill is passed the Corporation should not lay down and work the tramways, but that the undertaking should be leased to a company.

The Reported London Monorail.—It was reported on Tuesday that the South-Eastern Railway Company intended shortly to adopt the Behr monorail system between London Bridge and Cannon-street in order to relieve the congested traffic. The report further stated that Cannon-street, as a wayside station, would be partially abolished, and that it would be treated as the terminus of a branch line. Charing Cross, greatly enlarged, would then become the terminus, and trains would run direct from London Bridge. Communication between London Bridge and Cannon-street would be maintained by electricity on the Behr monorail system, the track running above the existing lines sufficiently high to clear the tops of the carriages. By this means, it was said, the chief cause of the delay on the South-Eastern would be removed. Mr. Vincent Hill, general manager of the South-Eastern and Chatham Railways, however, has informed a *Daily Chronicle* representative that his directors do not contemplate making the change indicated above. The matter was brought before them by Mr. Behr, and talked over; but there the matter ended. In the meantime the company will continue to do its best to serve its travellers with the means now at its disposal, the monorail system being, in the opinion of the directors, a dream of the future.

Cardiff.—The work of laying the crossing in Cowbridge-road is practically completed, and all is ready for the inspection of the Board of Trade representative. For the Royal Show an arrangement has been agreed upon between the tramway company and the Corporation, under which the company shall be allowed to run their trams through Cathedral-road on payment of a royalty. At a meeting of the Tramways Committee on Friday the correspondence that had taken place between Mr. Harpur and Mr. Glenn (the latter acting on behalf of the tramways company) was read. The Mayor said there seemed to be some misunderstanding with regard to the Bute-street Bridge. All that was wanted was 1ft. difference in order to meet the Board of Trade requirements for the cars to pass under. The Electrical Engineer presented a report, which contained a statement to the same effect. He also produced designs showing alterations in the double-decked cars to meet the Board of Trade requirements with regard to the bridges. It was decided that Bute-road should be reduced 13in. under the bridge. The committee also decided to adopt single-decked cars for the Splott and Grangetown route, and not to go through Wood-street, etc., until after further consideration. The Cathedral-road section was inspected on Tuesday by Major Druitt on behalf of the Board of Trade.

Blackpool.—Mr. Quin, the electrical and tramway engineer, made a statement at the last Tramways Committee meeting relative to the breakdown of cars on the new Marton route. He had taken nearly 300 measurements of the new tramway, he said, and he found that in only five places was the line of the standard regulation gauge of 4ft. 8½in. At 273 places the line was from ⅛in. to ¾in. under the standard gauge. Most of the curves where greater width would have been beneficial were rather tighter than the rest of the line. The Borough Surveyor told the committee that the gauge used for this line was one of three that had been used by his predecessor. As a matter of fact, this gauge was only 4ft. 8$\frac{5}{16}$in. wide. It also transpired that the promenade line had been tested, and this was not of the standard width either. It was proposed that the wheels should be altered to the gauge of the rails. The committee also considered what developments of the system were desirable, and decided upon two extensions. The line from Talbot-square is to be continued along Talbot-road and New-road as far as the cemetery gates, this to be a single line and to form a 1d. stage. A connection is also to be made between the Lytham-road tram and the new line round Marton by way of Waterloo-drive. It was also decided to have about 20 new cars, but the question of whether they should be bogie cars was left over. A letter was read from the Board of Trade intimating to the Corporation that under no circumstances must they lay down any more tramway lines with the wide groove.

Digitized by Google

Salford.—The Salford Corporation, it is stated, are not at present inclined to decide upon a working agreement with the Manchester City Council upon the tramways question. The proposed arrangement between the two Corporations has, it is stated, fallen through after several private consultations, and it is understood that the Salford Corporation propose to run their cars independently of Manchester. The clause in the proposed agreement upon which the issue turned, it is said, runs thus: "The service of cars run by Salford in Manchester and the fares charged to be subject to the approval of the Manchester Corporation, and, similarly, the service of cars run by Manchester in Salford and the fares charged to be subject to the approval of the Salford Corporation." The clause was inserted with the object of protecting Manchester from any diversion of traffic from lines partly in Salford and partly in Manchester to lines wholly in Salford, and to prevent Manchester from neglecting those Salford routes which it had undertaken to work. The view taken by the Salford Corporation appears to be that the obligation to satisfy Manchester might prove burdensome, much more burdensome than the corresponding obligation upon Manchester. We trust that the two Corporations will shortly come to a settlement upon the point, in order that what threatens to prove a serious disorganisation of the tramway system in the district may be avoided.

London United Tramways.—The Select Committee of the House of Commons presided over by Sir John Kennaway has been engaged this week in considering the Bill promoted by the London United Tramways Company to construct further tramways in the neighbourhood of Putney, Richmond, Hammersmith, Shepherd's Bush, Kew, Hampton Court, etc. During the enquiry it was stated that the total number of passengers who had travelled over the 7½ miles of the company's line now being operated by electric traction during the past 10 weeks had been 5,048,200, which practically represented the entire population of London. The average number per day was 71 260. Mr. Clifton Robinson, managing director and engineer of the company, said that at present eight miles of line were being electrically worked with 100 cars. By July, 16 miles would be worked with 150 cars. If the present proposed extension were granted witness estimated that the company would carry 50,000,000 people, and if the whole of the company's scheme—involving 40 miles—were authorised, 150,000,000 passengers per year might be carried. Among the petitioners against the Bill are several of the water companies, whose chief objection is that the clauses which were to protect their pipes from electrolytic action were not sufficient. With regard to the opposition of the London County Council, it is possible that an arrangement may be come to with the promoters. It was stated on Wednesday that if the company were prepared to allow the piece of line over Hammersmith Bridge to fall in with other spurs in 1909, the Council would not object to the company's making the line, and in the face of this evidence the chairman adjourned the enquiry to see if a satisfactory settlement could be come to with regard to the point in question.

London County Council Tramways.—At next week's meeting the London County Council will be invited by its Highways Committee to seek powers in the next session of Parliament for the construction of the following new tramways: North of the Thames—(1) Seven Sisters-road (existing lines), *via* Amhurst-park to Upper Clapton-road (existing lines). (2) Chelsea Bridge (north end), *via* Grosvenor-road, to a point near Lambeth Bridge. (3) Hampstead-road (tramway terminus), across Euston-road and along Tottenham Court-road, to a point near Oxford-street. (4) Edgware-road (from a point near the Marble Arch), to the county boundary at Cricklewood. (5) Harlesden (near the county boundary), *via* Scrubbs-lane, Wood-lane, Shepherd's Bush-road, Brook Green-road, and Fulham Palace-road, to Putney Bridge. (6) Uxbridge-road (near the railway station), *via* Richmond-road, Netherwood-road, and Westwick-gardens, to Shepherd's Bush-road. South of the Thames—(7) (*a*) Clapham Common, south side (London County Council tramways), *via* Clapham Common, Battersea-rise, Wandsworth Common, north side, and East-hill, to West-hill; (*b*) West-hill, *via* Kingston-lane, to the county boundary. (8) (*a*) Deptford (London County Council tramways), *via* Blackheath road and hill and Shooter's Hill-road, to the Herbert Hospital; (*b*) Herbert Hospital, *via* Woolwich Common-road, the road to the west of St. George's (Garrison) Church into New-road, and thence along Thomas-street and Green's End, to Beresford-square, Woolwich, and returning along New-road and Mill-lane, to a point in Woolwich Common-road near Nightingale-place. (9) New Cross-road (London County Council tramways), *via* Lewisham High-road, Loampit hill and vale, Lee High road and Eltham-road, to a point near Wellhall-lane at Eltham. (10) Streatham High-street (London County Council tramways terminus), *via* Streatham High-road, to the county boundary at Norbury. The total mileage included in this scheme is 28 miles, which, with street widenings, is estimated to cost £1,326 206.

Metropolitan District Railway.—The Court of Referees, presided over by Mr. Parker Smith, at the House of Commons on Wednesday, heard an application on behalf of the Middlesex County Council for a *locus standi* to be heard against the Metropolitan District Railway Bill to empower the company to work their railway by electric traction. Mr. Balfour Browne, K.C., in support of the application, said the County Council had not appeared against the Bill when it was before the committee, as they did not know it would affect them in any way. Since the construction of the Central London Railway, however, and the serious complaints of the damage caused to buildings by the vibration, the Council had become afraid that by the introduction of electricity on the District Railway the County Hall at Westminster, under which the railway passed, would suffer damage. The railway company had applied to Parliament for further powers in regard to the raising of money, and the County Council considered it an opportune time to apply for leave to be heard, with the view to obtaining the insertion of such a clause as would make it absolutely necessary for the company to carry out their works in such a way as to cause no damage whatever. He believed this was possible by a system of multi-motors, motors distributed throughout the train, instead of having a locomotive. Counsel contended that the object of the company in introducing electric traction was to increase the speed of trains, and with that increase of speed there was certain to be a great deal of vibration. A similar application on behalf of the Corporation of the city of London was also made. It was stated for the promoters that the speed would not be greatly increased. On certain sections of the line they had already a three-minute service, and it was hardly possible to put on more trains than they had at present. The *locus standi* was disallowed in both cases. Counsel on behalf of the London County Council, however, was granted leave to appear on the point of the provision of workmen's trains, and the city of London obtained a *locus standi* on the question of construction, of ventilation, and running of workmen's trains.

London Underground Railways.—The Joint Parliamentary Committee which has under consideration the question of routes for new tube railways in London resumed its sittings on Friday last, when Sir Alexander Binnie, engineer to the London County Council, gave evidence. On the plans, he said, there were 24 authorised lines. All tube railways hitherto had a gauge of 4ft. 8in. It was desirable to carry the tubes through the clay, but portions of the City and South London were carried through water-bearing strata, and had to be worked on the compressed-air principle, which added enormously to the expenses. He was at present constructing tube railways through Essex Marshes, under the River Lea. To be successful, underground railways must run trains frequently and at considerable speed. As to interchange stations, the most frequented points were Piccadilly-circus, Charing Cross, the Law Courts, near Somerset House, the junction of Tottenham Court-road and Oxford-street, the Bank, and the Liverpool-street Station of the Great Eastern Railway. Therefore a central station was not necessary. Geologically there would be difficulty in the subsoil at Barking in the gravel, chalk, and intermediate and miscellaneous strata. Financially, entirely new lines and proposed new lines would require £19,226.000; new lines, not "entirely new" or "proposed," £5 728 000; other divisional items, £6,318,000, £5 259,000, £11,701,710—total, £48,638,000. This, witness considered, was a prospect too vast to contemplate. Many of the lines were in conflict with each other, and incompatible with any scheme. But the cost of practical lines was compatible with low fares and fair return to the investor. Total cost of construction would in some cases be £400,000 per mile. On Tuesday was heard the case for the Charing Cross, Euston, and Hampstead Railway scheme, to which there was no opposition offered. It was stated that whatever conditions the Vibration Committee may impose, the promoters will be prepared to insert clauses to that effect in the Bill. Mr. Cripps, parliamentary agent to the London County Council, then continued his evidence. The Council wanted to see that every £100,000 of capital represented 100,000 sovereigns put into the works. He was of opinion that the existing underground railways of London should be taken into consideration in sanctioning the proposed lines, and should be afforded protection, as a great deal of money had been expended upon them. The London County Council would like to see the Charing Cross, Euston, and Hampstead Railway constructed. Witness said the north-eastern district was more in need of railway accommodation than was Hampstead. It would be difficult to raise the capital for tube railways in the ordinary way, and it might be necessary, therefore, that outside assistance should be sought. The committee adjourned.

LIGHTING AND GENERAL.

Dumbarton.—The Town Council intend to petition against the Clyde Valley Electric Power Bill.

Kirkintilloch.—The Council are continuing their opposition to the Clyde Valley Electric Powers Bill.

Kinning Park.—The electric lighting of the burgh by the Glasgow Corporation is under negotiation.

Southend.—The Town Council have obtained sanction to borrow £40,000 for electric lighting purposes.

South Shields.—Mr. J. H. Cawthra, borough electrical engineer, Swansea, has been appointed borough electrical engineer.

Cleveland and Durham County Electric Power Bill.—This Bill has been read a third time in the House of Commons.

Bacup.—The Council have accepted the offer of the Lancashire Electric Power Company for a supply of electricity in bulk.

Seaton Delaval.—The proposal to light part of the district will be discussed at a meeting of the Parish Council in November.

Birstall.—The Bill to confirm the Birstall electric lighting provisional order has been read a first time in the House of Lords.

Swadlincote.—The Urban District Council have resolved to provide additional electric lighting accommodation at Stanton.

Lichfield.—The Bill to confirm the Council's provisional order has been reported to the House of Commons without amendment.

St. Austell.—The Bill to confirm the provisional order relating to electric lighting at St. Austell has been reported for second reading.

Digitized by Google

Brierfield.—We understand that Mr. A. G. Cooper, of Colne, is preparing an estimate of the probable cost of electric lighting for the Council.

Copper.—It is reported that the shipments of copper to the United States for electrolytic purposes have for the time being entirely ceased.

Share Market.—During the past week there was little change in electric shares, with the exception of traction preference shares and debentures.

Ashton.—The electrical engineer is preparing specifications, etc., for a surface condenser to be installed at the Corporation electricity works.

Ormesby.—The Urban District Council have decided to petition in favour of the Cleveland and South Durham Electric Power Bill in the House of Lords.

W. T. Glover and Co., Limited.—The debenture stock transfer books of the Company will be closed to June 30 for the preparation of the interest warrants.

Abersychan.—The Westlake Brewery Company, Cwmavon, are making enquiries with regard to their power to supply Cwmavon with electric light. Lamps of 16 c.p. will be used.

Stratford-on-Avon.—The Bill to confirm the Council's electric lighting provisional order has passed through the Unopposed Committee of the House of Commons without amendment.

Chelsea Electricity Supply Co.—The transfer books of the preference shares, ordinary shares, and debenture stock will be closed to July 2 for the preparation of dividend and interest warrants.

Dundee.—The Dundee Horticultural Society have resolved to light the forthcoming flower show on Magdalen Green with electricity, the work being given to Messrs. James Maxwell and Son, King's road.

Stock Exchange.—The Stock Exchange Committee have ordered Castner-Kellner Alkali Company's further issue of £100,000 4½ per cent. first mortgage debenture stock to be quoted in the official list.

Eastern Extension, Australasia, and China Telegraph Co.—The directors have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share, free of income tax, payable on the 15th prox.

Penzance.—An offer from Edmundsons' Electricity Corporation, setting forth the terms on which they would be prepared to take over the electric lighting in Penzance, is being discussed by the Electric Light Committee.

Orrell.—At last week's Council meeting a letter was read from the Lancashire Electric Power Company, asking for an early interview with reference to the supply of electric power to Orrell. It was decided to leave the matter over for the present.

Argentine.—The Argentine Government has decided to ask Parliament for a credit of £70,000 for the construction of a cable between Chilecito and the Famatina Mines. This undertaking is regarded as real progress in mining industry in Argentine.

Llandudno.—The District Council have decided to apply to the Local Government Board for power to borrow £3,621 to cover money expended over and above the loan received for electric lighting purposes, and the probable amount required within the next two years.

Weston super-Mare.—We understand that Mr. Hawbayne has been asked to prepare specifications of the works of lighting the new pavilion with electric light. The District Electric Supply Company have also been requested to quote a price for supplying current to the pavilion and new swimming-baths.

Heywood.—The Electric Lighting Committee have resolved to undertake the wiring of consumers' premises and the supply of electrical fittings, including motors, on the deferred payment system. The clerk of works is endeavouring to obtain from manufacturers of electric motors particulars of price.

Teddington.—The London United Tramways Company have informed the Council that they are unable to give any further definite information at present as to the supply of electric current for lighting purposes. A letter from Edmundson's Electricity Corporation is before the Electric Lighting Committee for report.

Heating.—It is reported that the majority of the bed and dressing rooms in the King's apartments at Windsor are to be heated by electric stoves, each consisting of four large incandescent burners about 1ft. long. The burners are set in a burnished copper reflector, similar to the reflecters used in some forms of gas-stoves.

Blackrock.—The Dublin Electric Lighting Committee have informed the Urban District Council that they are prepared to enter into arrangements for the supply of current for the purpose indicated on the completion of the new electrical plant at the Pigeon House, which they hope will be in working order in a little over 12 months from now.

"Photographic Chronicle."—The first number of this new journal, devoted to the commercial and recreative branches of photography, has just been published, and promises to be an acquisition to the ranks of technical journalism. It will be published on the 1st and 15th of each month, at 2d., by Dean's Publishing Company, Chancery-lane.

Grimsby.—Mr. Vignoles in his last report states that since the last meeting 1,000 lamps had been connected, and he knew of nearly 1,800 more that would be required. The total number of lamps being wired and connected was 7,914. Financially, the committee had made a profit of £34. 17s. 6d. on the working expenses for the 8½ weeks ending May 30.

Bo'ness.—At a recent meeting of the Town Council it was agreed to suspend negotiations with Messrs. Crompton and Co., in connection with their proposal to light the town by electricity. It is proposed to appoint an electrical engineer to visit the burgh and report as to the advisableness of adopting the electric installation in Bo'ness; also to give the comparative cost of gas and electricity.

Tyne Commission.—The War Department have obtained permission to lay two submarine electric cables on or across the bed or foreshore of the River Tyne at the Narrows, also underneath the Commissioners' railway leading to the south groyne, and thence across the northern end of the Herd Sand, the total distance to be traversed by the submarine electric cables to be about 2 010ft.

Greenwich.—The Borough Council have, in view of the application of the City of London Electric Lighting Company, Limited, to the Board of Trade for a provisional order to empower that company to supply electric energy for all purposes throughout the whole of the area of the borough, referred to the General Purposes Committee to consider the whole question of electric lighting of the borough.

Harnessing the Mountain Torrents.—The Davos power scheme is being revived, and it is stated that the powers governing that famous health resort are seriously contemplating the total abolition of all forms of fuel in favour of an electric installation on a gigantic scale. The scheme, which will cost £340,000, is to utilise the motive power of two neighbouring mountain torrents to generate sufficient electricity.

Wakefield.—The Electric Lighting Special Sub-Committee have recommended that, in order to adopt the present plant for power purposes, the electrical engineer be instructed to have the No. 4 engine altered to a two phase plant, at an estimated cost of £600, and that tenders for carrying out the work be obtained and left in the hands of the chairman, deputy-chairman, and engineer to deal with.

Aldrington.—The Hove Town Council have appointed Messrs. Handcock and Dykes, Westminster-chambers, 1, Victoria-street, S.W., to prepare plans sections, estimates, etc., to support an application to the Local Government Board for sanction to borrow the necessary amount required to give effect to the Aldrington electric lighting order, and also to obtain the consent of the Board of Trade to the scheme.

Kingstown (Dublin).—We referred last week to the plans which have been prepared for an electric light installation in the township. The engineer estimated that the scheme would cost £50,000, but the contractor was prepared to execute the work for £45,000. When the matter came before the Council this week the scheme was discussed at length, and ultimately a motion was carried postponing its consideration for a month.

Stafford.—The accounts of the electricity department for the year ended March 31. 1901, show that the electrical energy generated amounted to 261,599 units, being an increase of 143,250, or 121 per cent. over the previous year; the equivalent in 8-c.p. being 10,813, or an increase of 2 255. The total revenue amounted to £2,532 16s. 6d., being an increase of £760. 0s. 11d.; the expenditure was £1,925. 0s. 11d., of £718. 18s. 10d. The gross profit is £607. 15s. 7d.

Personal.—Mr. W. W. Alston, of the Bury Corporation electricity works, has been appointed assistant electrical engineer at King's Lynn under Mr. John Pilling, A.M.I.E.E.—Mr. A. J. Ostler, of West Ham electricity works, has been appointed to the post of charge engineer at the electricity works of the Bristol Corporation under Mr. Faraday Proctor, A.M.I.C.E. and M.I.E.E.—With reference to a personal paragraph in last week's issue, we are informed that Mr. L. P. Greig was, before his appointment to Bury St. Edmunds, assistant installation inspector under the superintendent of mains at Edinburgh.

Wireless Telegraphy.—The Admiralty have ordered some 60 sets of wireless telegraphic apparatus to be made according to their own system and specifications for use on battleships and cruisers. The delicate part of the work has been placed with Mr. W. H. Sullivan, of Great Winchester-street. According to the *Globe*, Colonel Pilsoudski, of the Russian army, has just succeeded in transmitting a telegram without the use of a wire by utilising the conductivity of the earth. The journal says that the insignificant force which will transmit through air a distance of only 50m., will allow transmission through the earth for a distance of 550m.

Nantwich.—The Council have adopted a report of the Electric Lighting Committee recommending that the engineers be informed that the committee would be prepared to recommend the Council to approve the preliminary plans, estimates, and report of the engineers as to the proposed electric light works, mains, and refuse destructor subject to the modifications agreed upon by the committee with the engineers as follows: an accumulator to be put in instead of the small set of engine and dynamo for night load in connection with the sewage pumping station; eight arc lamps to be taken out of the scheme of street lighting. The total cost to be as follows: electric light works and mains. £12 505; refuse destructor. £1,275—total capital outlay, £13,780. The laying of such of the mains included in the report and estimates as the Council on the recommendation of the committee or otherwise might determine not to proceed with in the first instance to be deferred for such period as might be determined; and that the engineers be requested to furnish a revised report in accordance with the terms of that resolution.

Digitized by Google

Buxton.—Electricity has much to answer for. When at a recent meeting of the Urban District Council it was mentioned that a summons had been served upon the clerk to appear before the magistrates for a nuisance arising through the chimney of the electricity works sending forth black smoke, one of the councillors said he had white cows at Fairfield, and it had turned them into black ones. Enough to turn anyone's hair grey.

Holidays in the Eastern Counties.—We beg to acknowledge receipt of an advance copy of the Great Eastern Railway Company's new hand-book, "Holidays in Eastern Counties," by Percy Lindley. Prominence has been given to some less known districts in East Anglia, and the illustrations throughout the little volume are many and of beautiful execution. Detailed information is given as to fares, hotels, golf links, etc.

Rowley.—At the last meeting of the District Council the Electrical Supply Committee reported that they had had an interview with Mr. McLean, the representative of the Midland Electric Corporation, to discuss matters connected with the carrying out of their undertaking provided in the provisional order passed in 1898. It was reported that a distributing station was about to be erected at Reddall Hill-road, Old Hill. The matter was referred back to the committee for further consideration.

Morecambe.—The Chairman of the Electricity Committee stated at the last meeting that there had not been much more than half the current consumed that they expected owing to the bad season and other causes. A great hardship to the undertaking was that the repayment of the loans had to be made in 25 years. For the gas undertaking a period of 50 years had been allowed, and if the same period had been allowed to the electricity undertaking, it would have been relieved to a very great extent.

Beckenham.—The Electric Lighting Committee are willing to extend arc lighting in main roads as soon as the new machinery (on order) rendered such extension possible. The British Insulated Wire Company, Limited, have offered to charge 2d. per unit for current used for motors, with a reduction of 1½d. per unit where so used on an average for six hours a day. The company have also agreed to reduce the charge for current to the institute and baths to 4½d. per unit. It is stated that the electric light extension will be ready by next January.

Hull Telephones.—The Hull Corporation Telephone (Special) Committee have resolved to recommend the City Council to make application to the Postmaster-General for a license to establish a municipal telephone exchange to expire in 1911. They will also approach the Post Office as to the terms on which they would be prepared to sell their telephone plant. In reply to the canvass, 354 persons are prepared to become subscribers for 1,029 instruments, and it is stated that the Local Government Board are prepared to sanction the borrowing of a loan for the purpose of establishing the exchange.

Leyton.—Mr. Hawkes, of Leyton, recently obtained an order in Chancery restraining the Leyton Urban District Council from continuing a nuisance arising from the use of gas engines for the generation of electric light. The Council abated the nuisance in part by substituting steam-engines for some of the gas-engines, but Mr. Hawkes obtained a sequestration order for non-compliance. The Council then obtained an extension of time. Lords Justices Rigby, Collins, and Romer have now granted the Council a further extension for 18 months on the ground that it would take that time to replace all the gas-engines by steam-engines.

Walsall.—The last report of the Electric Light Committee shows that the total number of consumers supplied on May 31 last was 186. The total output from the main generators was 26,406 units. The machinery has been run for 423 hours during the past month. The committee have approved of part of the corporate land fronting Freer-street, forming part of the pig market, with the building thereon formerly used as a weights and measures office, as a site for the new transformer sub-station, and instructions have been given for tenders to be obtained for carrying out the structural alterations necessary to make such building suitable for the purposes for which it is required.

Inverness.—The Town Council have adopted a recommendation of the Electric Light Committee with regard to the question of obtaining water power for electric lighting purposes in the burgh. The burgh engineer submitted a plan in connection with the proposal to obtain a supply of water from Loch Dochfour, and said he thought the cost of bringing the water in a conduit or series of pipes to the works would be within £20,000. Mr. James Fraser, C.E., Inverness, has been instructed to prepare a preliminary plan, section, and outline of a water-power scheme that would enable the Council to treat with the Caledonian Canal Commissioners and owners of land; and also, if Mr. Fraser saw fit, to report on any other source of water power.

Bedford.—The Urban District Council propose to alter the present method of payment to the electrical engineer of salary and commission to a fixed annual salary, but have not come to terms as yet. The electrical engineer has been instructed to obtain one dozen five-ampere meters at £45, and 50 pairs of service cut-outs at an estimated cost of £14. The following motions will come before the next meeting of the Council: "(1) That it be an instruction to the Electric Lighting Committee not to contract any debt on account of capital expenditure to be provided for out of loans, until such loans shall have been sanctioned by the Council and the money received. (2) That until the present capital expenditure of £85,000 be made remunerative, no further loans be applied for."

Alloa.—Mr. Hogarth, of Messrs. Buchan and Hogarth, Edinburgh, the Council's electrical engineers, made a statement at the last meeting of the Town Council with reference to the progress of the arrangements relative to the introduction of the electric light, and he also submitted estimates for the cabling of the scheduled parts of the town, and for a supply of electric lamp pillars. The tenders recommended for acceptance by him were approved of, and it was mentioned that the work of laying the cables would be proceeded with in the course of the next two months. Authority was also granted the Electric Light Committee to arrange as to the formation of private connections, and also obtain an estimate for the lighting of the town hall and the municipal buildings.

Keighley.—The mayor and the mayoress (Mr. and Mrs. H. C. Longedon) the deputy-mayor and the deputy-mayoress (Alderman and Mrs. B. S. Brigg) on Saturday assisted at the opening of the electric lighting of the town. About 9 45 the mayoress proceeded to the box opposite the end of Hanover-street, and switched on current to Cavendish street, Low-street, East-parade, the railway bridge, and Church-green. The party afterwards drove to the electric lighting station at Low Bridge, where further ceremonies were performed. The two engines and dynamos were started by the deputy-mayoress and the mayoress respectively, whilst Mrs. W. Clough (wife of Alderman Clough) set the electric motors into motion from the switchboard. After the usual toasts had been proposed and responded to, the party made a tour of inspection through the works under the guidance of Mr. J. M. Smyth, the electrical engineer.

King's Lynn.—Applications have been received from private consumers for 8,629 lamps of 8 c.p. or equivalent, being an increase of 100 lamps during the month and the street lamps for Wisbech-road and Diamond-street have been fixed. The chairman and electrical engineer have been asked to report in reference to additional lamps required for lighting Gaywood-road; the engineer is also to submit a report showing the cost of lighting the public walks. Eight lamp posts are to be erected for lighting Hardwick-road. Under the revised charges for current to churches and chapels the price per unit will average about 4 6d., this price comparing favourably with the prices in other towns where special rates are offered. The engineer has reported that Mr. E. T. Williams had sent in his resignation he having been appointed assistant engineer at Belfast electricity works, and that advertisements had been issued for an assistant engineer to fill the vacancy at a salary of £80 per annum. Three candidates are to be selected to appear before the committee.

Coventry.—The annual report of the Electric Light Committee contains the following: "The number of customers has increased from 226 to 331 during the year, and the lamps connected from 17,906 (8 c.p.) to 23,637, and further connections are being made. The number of units sold has increased from 229 697 to 341,810, and the revenue from sale of current and meter rental from £4,188. 16s. 7½d. to £6 053 17s. 3½d. The increase in units sold to private consumers has been from 169 056 to 268,982, and the revenue from this source is £5 120 18s 6d, against £3 500 8s. 4d. The profit on working is £1,528. 18s. 2½d., against £786. 19s. 8½d. This would have been substantially greater but for the rise in the price of coal. The capital charges amount to £3,789. 14s. 2d. The sinking fund charge has been increased by the amount payable in respect of the capital expended during the previous year. The net charge on the rates is £2 250. 15s. 11½d., against £1,745. 5s. 5½d. last year. The whole of this sum, except £553. 10s. 3d., has been raised by means of rates already made."

Indian Bills and Telegraphic Transfers.—In the House of Commons on Monday Sir Edward Sassoon asked the Secretary for India whether he was aware that the difference of a sixteenth of a penny ordinarily made by the India Council between the sale of bills and telegraphic transfers represented a charge of 9½ per cent. per annum; and whether, in view of this impost upon banking and commercial transactions, he would give instructions for reducing the difference by one moiety, except on occasions when conditions of financial stringency prevail in India. Lord George Hamilton replied that the difference of a sixteenth of a penny per rupee between the price of bills on India and that of telegraphic transfers represented a charge of 9½ per cent. per annum, if it could be assumed that all such bills, whether drawn on Calcutta, Madras, or Bombay, could be presented in 15 days, but this was not the case. To give the telegraphic transfers at only one thirty-second of a penny more than bills, would, with the present rates of discount, be in effect to lend the money at cheaper rates than that at which the Presidency banks were lending it.

Newark.—Colonel Durnford has held an enquiry into an application by the Town Council for sanction to borrow £30,000 for the purpose of the electric light. Mr. Vesey Brown gave some particulars as to the scheme, which is estimated to cost £27,250, with £2,750 engineering expenses and contingencies. The supply will be on the three-wire continuous-current system, with 460 volts between the outer conductors. The cables will be laid solid in wooden or iron troughing. Three engines of the high speed enclosed type are proposed, the dynamos being coupled direct. An economiser will be used in conjunction with the three boilers. A storage battery will also be provided, also the necessary switchboard and motor-generators. The number of 8-c.p. lamps which the installation will be able to supply will be approximately 16,000. The estimated number of consumers when the plant is completed is 300. An estimate has been made by which it has been shown that the annual expense of maintaining the plant, including interest and sinking fund, will be £4,000 per annum, when 250,000 units are sold, and the revenue at an average price of 5d. per unit will be slightly over £5,200 per annum. The public lighting will be by means of incandescent lamps.

Yarmouth.—The Town Council have adopted a report from the Electric Lighting Committee, containing the following report of the borough surveyor: "Since the last report applications have been received from 46 customers for 1,399 lamps, making a total of 521 customers for 25,968 lamps of 8 c.p. The borough accountant has now made up the accounts for the past year, and instead of submitting an estimate of the quarter's working, I am able to present the actual results of the 12 months, which I regret are not so satisfactory as I had hoped. The income for the year has been £7,225, the working expenses £5,406, leaving £1,819 to pay interest and sinking fund, and as these, with some other small items, amount to £2,570, there is a deficiency of £751. This will not fall upon the rates, as there was a balance last year of £371; and a sum of £380 will be carried forward to next year's account. This result has been caused by the high price of coal, which has made the production more costly by about £650, and the reduction in price to customers—made before coal was increased in price—amounting to £900; but this reduction resulting in the large number of additional lights put on by existing customers, and the 111 new customers obtained during the year, will in the end quite recoup the Council, and with the reduced price of coal I anticipate that this loss will be fully met in next year's account. The capital outlay on the works on March 31 last was £44,392, and the sinking fund towards its repayment £5,789. Of this sum £3,896 has been paid out of the profits earned, and £1,893 in the first three years' working, paid out of the rates. The sum contributed to the rates of the town this year on the assessment of the undertaking has been £201." Loans to the amount of £67,000 have been sanctioned, of which £43,995 has already been borrowed.

Sheffield.—At the last meeting of the council of the Sheffield Chamber of Commerce the reply of the Postmaster-General to a letter sent to him on the subject of the interruption of telegraphic communication by storms was read. His Lordship, after pointing out that it was the practice of the Department whenever the service was interrupted by a storm to give notices of delay for public information, and that by the use of stouter timber and reserve wires much had been done to provide against interruptions, referred to the provision of underground lines. The great costliness of guttapercha-covered wire and its electrical defects had until recently stood in the way of its being used except to a limited extent. The introduction of the paper-insulated cable, which was both cheaper and better from an electrical point of view, had, however, enabled the Department to construct the important experimental underground line between London and Birmingham, and the line had already proved of great advantage during the storms which occurred last year. It was subject to some drawbacks, but the Postmaster-General felt justified in extending it further northward, and sanction for the necessary expenditure would be sought. He was not without hope that some of the difficulties and drawbacks still connected with an underground system would be surmounted, and that the Department would be justified in further extending it. But it was necessary to proceed with caution. Another letter mentioned the places on the Continent to which telephone and telegraph cables and direct wires are now laid, and stated that the Government was in negotiation with the Italian Telegraph Administration respecting a direct wire to Milan. The amount of telegraph traffic was not sufficient to justify the establishment of a direct wire to Munich, nor did the Postmaster-General feel that he could with propriety make representations to the French Telegraph Administration respecting the provision of direct wires between Havre and the cotton-manufacturing towns in the North and East of France. As regarded telephonic communication between provincial towns in England and France, he was in communication with the authorities, and hoped it would be possible before long to bring this extension of the service into operation. The question of a decentralisation of the central telegraph office in London had for some time been receiving careful attention. No definite decision had yet been arrived at in the matter, but all that was possible would be done for the acceleration of the foreign telegraph traffic at present passing through London. On the question of the provision of direct wires from provincial centres in England to the Continent, he did not see his way to arrange for the establishment of any additional wires of this description, with the possible exception of one between Liverpool and Paris.

Wolverhampton.—The Town Council on Monday adopted the following report from the Lighting Committee on the past year's working of the electricity undertaking: "The net result, after payment of interest and sinking fund charges, is a loss of £130. 16s. 6d. In explanation of this, it should be pointed out that the sum of £545. 18s. 3d. has been expended during the year out of the revenue of the department in respect of the 'change over' of the system of supply, sanctioned by the Council in November, 1898. In addition to this, the average price obtained per unit during the past year has been only 4·31d., as against 4·815d. during the previous year, and this decrease in the selling price of the electrical energy produced during the year ending March 31, 1901, represents a loss of revenue amounting to £1,166. This decrease in the price obtained is due to the reduction in the charge for electricity made by the Council on July 9, 1900. It will be seen that if the cost of the change over (£545. 18s. 3d.) is included, the net profit for the year would have been £415. 1s. 9d. It should also be pointed out that the increase in the price of fuel has had a most adverse bearing upon the financial result. This item alone accounts for an additional expenditure of £592. 2s. 5d. over the amount that would have been paid had the price remained as during the previous year. Moreover, owing to the non-delivery of the new generating plant, ordered in October, 1899, your committee have been unable to complete the change over of the system of supply, and it has therefore been necessary to keep two distinct systems in operation during the whole of the past year, with a consequent increase in the working costs. The amount charged to revenue in respect of the sinking fund on capital, has been increased during the year by £845. 3s. 11d. in respect of the first instalment on the £28,870 loan, which loan is, as yet, only partly productive. Having regard to the foregoing facts, your committee are of opinion that the result of the year's working is very satisfactory, and shows that the undertaking is in a sound financial condition. It is hoped that the change over of the system will be completed during the ensuing year, and that the current year will be the last occasion upon which the revenue of the department will be charged with any costs in respect of this. Your committee again desire to call attention to the satisfactory growth of the undertaking. From the following figures it will be observed that the amount of electricity sold, the increase in the number of consumers, and lamps connected compare very favourably with previous years:

Year.	Consumers.	Increase. %	Lamps connected.	Increase. %	Units sold.	Increase. %
1st ...	113 ...	— ...	8,941 ...	— ...	191,701 ...	—
2nd ...	154 ...	36 ...	11,307 ...	26 ...	224,709 ...	17·2
3rd ...	208 ...	35 ...	14,151 ...	25·2 ...	291,233 ...	29·55
4th ...	276 ...	32·7 ...	19,932 ...	40·8 ...	371,830 ...	27·5
5th ...	364 ...	32 ...	25,184 ...	26·3 ...	482,247 ...	29·7
6th ...	461 ...	26 ...	33,833 ...	34·42 ...	633,508 ...	31

The supply of electricity for motive power purposes is also increasing in a satisfactory manner, and your committee have reason to hope that this branch of the undertaking will prove both a great convenience to the users of power within the borough, and also be a source of profit to the Corporation. Rapid progress is being made in the electric lighting branch of the undertaking, especially in the residential districts, 19 private consumers having been connected to the mains during the past year's working. Your committee are contemplating considerable extensions of mains in various portions of the borough during the present year, and it is expected that the results obtained therefrom will fully equal, if not exceed, the results achieved by the progressive policy of your committee in the past."

London County Council.—The Council at Tuesday's meeting agreed to lend the Hackney Borough Council £50,000 for electric light installation and street-lighting purposes; the St. Pancras Borough Council £50,000 for electric light installation; the Southwark Borough Council £13,980 for the same purposes; the Hampstead Borough Council £9,525 for the same purposes; and Stepney Borough Council £380 for electric light extensions. The Highways Committee recommended that the Council should instruct the Parliamentary Committee to prepare the draft of a Bill, on the lines of the suggested clause agreed to at the recent conference of local bodies, relative to the purchase by local authorities in combination with each other, or by the London County Council, of undertakings for the supply within the county of London of electricity in bulk; and that such Bill should be submitted, in draft, for the consideration of the Corporation of the city of London, and the respective councils of the city of Westminster and of the several metropolitan boroughs. This report was adopted. The Parliamentary Committee desired to be authorised to seek legislation in the next session of Parliament to empower local authorities in London supplying electricity for lighting purposes to wire and fit consumers' premises for electric lighting, on such terms as they may decide upon, and to empower the Council to lend, and the local authorities to borrow, money required for carrying out such work. The same committee also recommended that a petition be sealed and presented, if necessary, against the Notting Hill Electric Lighting Company's Bill in the House of Lords. The following notices under Electric Lighting Acts and Orders were agreed to: Blackheath and Greenwich District Electric Light Company, under the Blackheath and Greenwich District Order, 1897, to lay low-tension mains along Wemyss-road, Royal-hill, and Ulundi-road. Charing Cross and Strand Electricity Supply Corporation (1) under the Strand District Order, 1896, to lay mains from the company's station in Maiden-lane, along that thoroughfare and Chandos-street; (2) under the St. Martin's District Order, 1889, to lay mains along Chandos-street, Bedfordbury, New-street, and St. Martin's-lane, to the company's station there; (3) under the City of London Order, 1899, to lay mains along the Queen Victoria-street subways from Lambeth-hill to the eastern end of Queen Victoria street, and to make connections from the subways at certain points. County of London and Brush Provincial Electric Lighting Company, under the Camberwell Order, 1896, of intention to lay low-tension mains along both sides of Chumleigh-street, and to lay high and low tension mains across Rye-lane and along a portion of Elm-grove, and to construct a transformer box in Elm-grove; also under the Wandsworth Order, 1892, to lay high and low tension mains along Venn-street and across High-street, and low-tension mains along Clapham Common (south side), and to construct a transformer box in Venn-street. Metropolitan Electric Supply Company, under the Paddington Order, 1890, to lay high-tension mains along Sutherland-avenue, Foscote-road, and Amberley-road. St. Pancras Borough Council, under the St. Pancras (Middlesex) Order, 1883, to lay mains along portion of James-street and Gordon-square. County of London and Brush Provincial Electric Lighting Company, under the County of London (North) Order, 1892, to lay power and low-tension mains along Hermes-street, from Pentonville-road to Hermes-hill. The London Electric

Digitized by Google

Supply Corporation, under its order of 1889, to lay distributing mains along Mermaid-court, Tennis-court, Bowling Green-lane, and across Newcomen-street. The Metropolitan Electric Supply Company, under the Paddington Order, 1890, to lay high-tension mains across and along a portion of Harrow-road, across Westbourne Park-road, along a portion of Talbot-road, and along Porchester-terrace; under the West London Order, 1889, to lay low-tension mains across and along a portion of Edgware-road. The Notting Hill Electric Lighting Company, under the Notting Hill Orders, 1889 and 1895, to lay mains of low and extra high tension along Napier-road, and low-tension mains along Addison-road, Kensington-road, Russell gardens and road, and Holland-road. St. Pancras Borough Council, under the St. Pancras (Middlesex) Order, 1883, to lay mains along a portion of Gaisford-street. The Council further received notices as follows, served under orders granted to local authorities, and under which the Council has no power of approval or disapproval of works: from the Hammersmith Borough Council, under the Hammersmith Order, 1893, to lay mains along Coverdale-road, along Ravenscourt lane and square, Ashchurch-grove, Askew-crescent (south and east sides), Poplar-grove, Cromwell-road, Richmond-gardens, Roseford-gardens, Camden-gardens, and Cambridge-road, Aide-road, Agate-road, and Beauclerc-road; from the South London Electric Supply Corporation, under the Lambeth Order, 1892, to lay mains of high and low tension along both sides of Rosendale-road, Dalmore-road, Eastmearn-road, Buccleugh-road, Chancellor-road, Mytton-road, Martell-road, Paget-road, Carson-road, Park-road, and Chestnut-road; from the Woolwich Borough Council, under the Plumstead Order, 1899, to lay mains along portions of Cambridge-place, High-street, Plumstead, and Walmer-road.

PROVISIONAL PATENTS, 1901.

JUNE 10.

11838. Improvements in regulators for electric or other meters operating air or other fluid compressors. Philip Middleton Justice, 55, Chancery-lane, London. (The "Long Arm" System, United States.)

11845. Improvements in or relating to electric wire switch couplings. Alfred Jewell Adkins, 59, Walham grove, Walham Green, London.

11847. Improvements in or relating to electrostatic instruments. George Leonard Addenbrooke, 37, Essex-street, Strand, London. (Complete specification.)

11854. Improved automatic electric cut-out for overhead wires or conductors. David Alaxanda Lowery, 18, Buckingham-street, Strand, London.

11857. Improvement in armature windings for dynamo-electric machines. Engelbert Arnold and Friedel Collischonn, 47, Lincoln's-inn-fields, London.

JUNE 11.

11922. Improvements in or relating to electric meters, meters, and methods of compensating for phase-displaced currents. Ludwig Gutmann, 6, Lord-street, Liverpool. (Complete specification.)

11925. Improvements in apparatus for connecting the ends of electric cables and the like. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Francis H. Stillman, United States.) (Complete specification.)

11931. Improved method of regulating and controlling the speed or power of electric motors. Walter Lacy Allcroft, 166, Fleet-street, London.

11949. Improvements in electric telegraph apparatus. Freeman Howard Littlefield, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

11951. Ampere-meter for the registration of the maximum consumption of electrical energy. Hugo Helberger, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JUNE 12.

11992. Improvements in means for accentuating electrical contacts. The British Thomson-Houston Company, Limited, Bush-lane House, Cannon-street, London. (Elihu Thomson, United States.) (Complete specification.)

12016. Framework for alternating-current electrical machines. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktiengesellschaft, Germany.) (Complete specification.)

12020. Improvements in electricity meters. George Hookham, 18, Southampton-buildings, Chancery-lane, London.

12023. Improved mechanically-operated and electrically-controlled alarm apparatus. Wladislaw Kielpinski, 322, High Holborn, London. (Complete specification.)

JUNE 13.

12061. Improvements in etheric telegraphy. The Scottish Wireless Electric Syndicate, Limited, and Walter Jamieson, 53, Bothwell-street, Glasgow.

12069. Improvements in automatic electrical signalling apparatus for railways. James Ernest Spagnoletti, 53, Chancery-lane, London.

12071. Electrical ignition and valve-operating mechanism for oil or petrol engines for motor cycles. Silvain de Jong, 5, Budge-row, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Dec. 22, 1900, being date of application in Belgium.) (Complete specification.)

12088. Improved method of and means for taking electric current from transformers. Gustave Weissmann, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, Dec. 5, 1900, being date of application in France.)

12094. Improvements in electric cables. Francis Tremain, 70, Palace chambers, Westminster, London.

12119. A new or improved method of and combination of apparatus for translating and relaying telegraph cable signals. John Peter Gorton, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

JUNE 14.

12121. Machinery for pressing the copper segments and insulating strips of electric commutaters into annular form. Albany Francis Petch, 42, Florence-road, Finsbury Park, London.

12134. Improvements in or relating to electric arc lamps and electrodes therefor. Charles Andrew Lee, 56, Paulton's-square, Chelsea, London.

12139. An improved device for the prevention of accidents from overhead trolley wires. Clarence Jones, 8, Clayton-street, Blackburn.

12153. Improvements in electrically-propelled cycles, auto-cars, and other like vehicles. Charles Adams-Randall, 5, Salters' Hall-court, London.

12195. Improvements in and in the construction of electrodes. William Phillips Thompson, 322, High Holborn, London. (Robert Jacob Gülcher, Germany.)

12210. Improvements in electrostatic separators. Clinton Emerson Dolbear, 46, Lincoln's-inn-fields, London. (Complete specification.)

12218. Improvements in electric clocks and automatic alarm transmission. G. B. Bowell, 40, Chancery-lane, London.

12220. Improvements in electric telegraphy. Philip Middleton Justice, 55, Chancery-lane, London. (The Rowland Telegraphic Company, United States.) (Complete specification.)

12223. Improvements in or connected with the field regulation of electro-dynamic machinery. James Cooper Wilson, Norfolk House, Norfolk-street, Strand, London.

JUNE 15.

12229. Improvements in ceiling roses for use in electric lighting. John William Gilbert, 60, Newhall-street, Birmingham.

12241. Improved manufacture of electric illuminating bodies. Wilhelm Boehm, 111, Hatton-garden, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on July 6.

1900.

4719. Electric meters. Marr and Laidler.

10940. Incandescent electric lamps. Swinburne.

12531. Positive electrode for accumulators. Von Sedneff.

12739. Dynamo brush. Ringsdorff.

12855. Manufacture of bulbs for electric incandescent lamps. Junge. (Oberlausitzer Glashüttenwerke Otto Hirsch.)

13081. Means for grinding and truing-up dynamo commutaters and the like. Purdy.

13722. Contact devices, chiefly designed for use in connection with electrical counting or recording devices. Staveley and Parsons.

14422. Switches and apparatus for use in starting and controlling electric motors. Adams.

14552. Conduits for electric conductors, water, or the like. Tugby.

14704. Transmitters for electrical waves or like apparatus. Braunerhjelm. (Date applied for under International Convention, Jan. 26, 1900.)

17379. Electric meters. Lake. (Soc. pour L'Exploitation des Compteurs Electriques Rittener et Cie.)

22851. Apparatus for automatically electrically collecting and conveying letters and other postal matter. Gordon.

1901.

367. Multiple wall connections for electric lighting, heating, and the like. Lundberg and Lundberg.

4494. Process for making electrodes for accumulators. Thompson. (Akkumulatoren und Elektricitäts-Werke Aktiengesellschaft, formerly W. A. Boese and Co.)

6870. Coin-controlled apparatus for telephones. Lewis.

6940. Audible electric telegraphy. Oxlade and Richardson.

8962. Switch apparatus for use in a surface-contact system of electric traction and operating switches used in such system. Parker.

NOTES.

Long-Distance Telephony.—A French electrical engineer, one Mr. Maiche, claims to have solved the question of telephoning by submarine cables to great distances. He has recently been carrying out some exhaustive experiments on the point, and it is stated that at Calais last Saturday Mr. Maiche succeeded in transmitting a telephonic message with perfect distinctness through a cable 400 miles long.

Royal Meteorological Society.—The closing meeting of this society for the present session was held on the 19th inst., when a paper by Mr. H. Helm Clayton, of the Blue Hill Observatory, U.S.A., on "The Eclipse Cyclone, the Diurnal Cyclones, and the Cyclones and Anti-Cyclones of Temperate Latitudes," was read, followed by a paper on "The Seismograph as a Sensitive Barometer," by Mr. F. Napier Denison, of Victoria, British Columbia.

Society of Arts.—We are informed that the council have awarded the society's silver medal to the following, among other, readers of papers during the session of 1900-1901: Mr. Fritz B. Behr, for his paper on "The Proposed High-Speed Electrical 'Monorail' between Liverpool and Manchester"; Mr. G. Marconi, for "Syntonic Wireless Telegraphy"; and Lieutenant Carlyon W. Bellairs, R.N., for "The Coal Problem: Its Relations to the Empire."

The American Institute.—The *Transactions* of the American Institute of Electrical Engineers for May include Dr. Arthur E. Kennelly's paper on "The New Edison Storage Battery," which was described in a recent issue of this journal, and which has aroused such widespread interest. Other features of this issue are the discussions on Prof. W. E. Goldborough's paper on "Air-Gap and Core Distribution," and Mr. Wm. Vansize's paper on "A New Page-Printing Telegraph."

Board of Trade.—The President of the Board of Trade has appointed Sir Alfred Bateman, K.C.M.G., the Comptroller-General of the Commercial, Labour, and Statistical Departments of the Board, to be chairman of the Advisory Committee on Commercial Intelligence in the place of the late Sir Courtenay Boyle, K.C.B., and Mr. H. Llewellyn Smith, deputy comptroller of the above departments, to be deputy chairman of the committee.

Dutch Automobile Endurance Contest.—An endurance contest, the date of which has yet to be decided upon, has been arranged by the Dutch Automobile Club of Holland. It is proposed to cover a distance of 330 miles, and the time allowed for the run will probably be four days. Speed, however, is quite a secondary consideration, for it has been decided that the highest average speed at which the cars may travel shall be 12½ miles per hour. The vehicles taking part in the trials will be judged according to the number and length of stops. Besides being open to all members of the Dutch Automobile Club, the contest, we understand, may be participated in by members of recognised foreign organisations of a similar character.

A New York Experiment.—An interesting experiment is now being made in New York in connection with the matter of obtaining a water supply for the condensing plant of the Edison Company at their new electrical power-house in course of erection at Thirty-ninth-street and East River. A huge 250ft. steel tunnel measuring 12½ft. in diameter and weighing over 1,000 tons has been built, and the intention is to sink the tunnel some 23ft. under water and to use it as a huge aqueduct to lead water from the river to the condensing plant referred to above. This experiment is looked upon by New York engineers as the forerunner of a scheme to tunnel the North River, and it is estimated that for an expenditure of about £750,000 the tunnelling of the river could be accomplished.

Telephones for the Police.—The question of connecting the police stations throughout the Metropolis with the telephone service was the subject of a question to the Secretary for Home Affairs in the House of Commons a few days ago. Answering Captain Norton, Mr. Ritchie said the matter had already been considered by the Department, and that it appeared that the existing efficient system of telegraphic communication between all the police stations, which was entirely under police control, met all police requirements. In view of the smart captures which have resulted from the introduction of the telephone into the provincial police stations, it is somewhat surprising to find the authorities adverse to the adoption of the system for police purposes within the metropolitan area.

Rapid Transit in Germany.—The elevated track of the military road from Berlin to Zossen, it is stated, will be the scene of the experiments which are to be carried out in August in connection with the projected electric railways in Germany. The proposal is to obtain a speed of 125 miles an hour on these lines. The elevated track in question has been specially strengthened to permit of the tests being made, and although it may be found that such a high speed as suggested is not feasible, the experiments will no doubt prove of the highest importance for the improvement of rapid transit. We understand that two cars will be employed, the construction and equipment of the one differing from the other in order to allow of manifold experiments being made. Each car will have four motors, aggregating from 1,100 h.p. to 3,000 h.p., two three-axle movable trucks, and the necessary transmitters, switching apparatus, etc. The cars will be 71½ft. long, weigh about 90 tons, and carry some 40 or 50 passengers.

The Telephone Company and Municipalisation.—The telephone competition at Tunbridge Wells is becoming keener and keener, with the result that the National Telephone Company has announced its intention of giving "an unlimited service for a penny a day" to its subscribers in that town. It was not until the introduction of the municipal telephone system into Tunbridge Wells that the company would listen at all to the idea of a reduction of the high tariff in vogue, and then its charge to subscribers was reduced from £8 to £4 a year. This concession, however, would not appear to have had the desired result, and apparently a further reduction of charge has become necessary in order that the company may offer any successful competition to the Corporation. It is stated, however, that the burgesses remain firm for the municipal undertaking, the number of subscribers on the Corporation list at present being 500. The charge for a connection with the municipal system now stands at the comparatively moderate figure of £5 a year, but there is reason to believe that this figure will be appreciably lowered before long.

Third-Rail Construction.—The *Electrical Review* of New York describes a new electric railway system which has just been patented by Mr. B. W. Tucker, of Newark, N.J., the improvement claimed relating more particularly to the construction of the third rail. In this case the third rail is composed of a casing made of non-conducting and non-magnetisable material, such as wood, and having a longitudinal groove formed therein. A U-shaped trough of suitable insulating material is placed in the groove, which is covered by a sectional conductor, each section being insulated from the others by interposed blocks of insulating material. Within the groove of the rail is placed the feed

Digitized by Google

wire, composed of a good conducting and magnetisable metal, preferably iron. This wire is made continuous, and to permit of its necessary expansion and contraction it is coiled or looped at intervals, these coils or loops fitting in depressions arranged in the lining of the rail. The car is provided with a magnet that attracts the wire and draws it into engagement with the sectional conductor or covering, a suitable brush being provided, which is in contact with the casing, for conducting the current to the motor.

Sports at Chelmsford.—At the invitation of Messrs. Crompton and Co., Limited, a large party of ladies and gentlemen journeyed down to Chelmsford on Saturday, the occasion being the annual race meeting of the Arc Works Athletic Club. Special saloon carriages were attached to the 10.55 a.m. train from Liverpool-street Station, and the 30-mile run to Chelmsford was made in good time. Here carriages were in waiting which conveyed the party to the extensive works of the company, and the best part of an hour was spent in looking over the shops. The site for the large extensions which are about to be taken in hand was pointed out, and we understand it is the intention of the company when the new buildings are erected to devote them solely to what is known as "precision" work, which at the present time is almost entirely left to our American cousins. An excellent luncheon was served at the old works close by, and the company then proceeded in carriages to the sports ground. Exceptionally warm weather favoured the excursion into the country, and if the heat was somewhat fatiguing, interest in the proceedings was in no way lacking. The day was a great success.

The Electrolysis Question. — The question of electrolytic action on water and gas mains arising from the introduction of electric tramways or an electricity supply into a locality, has been raised on several occasions this session before the House of Commons Committees appointed to enquire into Bills dealing with these matters. If we remember rightly, however, the applications of the gas and water companies for the insertion of clauses in the Bills for protection from possible electrolysis of their mains have failed in practically every case, and in this the London United Tramways Bill has proved no exception. In this case the Chelsea Water Company asked for protection against possible electrolytic action on their mains from the working of the electric tramways proposed to be introduced into the district under the Bill. It was a test case, and expert evidence was called to show that the only effectual protection against electrolysis was by using insulated returns on the tramways. On behalf of the promoters, however, it was urged that the Board of Trade regulations sufficiently protected the interests of the gas and water companies concerned, and this view was in the end fully endorsed by the committee's decision in their favour.

Aerial Transportation.—"Flying Machines and their Commercial Uses" is the subject of a short article in the current number of *Cassier's Magasine*. To begin with, we are told that the underlying principle of maintaining equilibrium in air is that the centre of pressure upon the sustaining surfaces shall at all times be upon the same vertical line as the centre of gravity due to the weight of the apparatus. In regard to the shape of surfaces to be employed, Lilienthal demonstrated that concave-convex wings, like those of birds, are far superior in supporting power to planes, and the latter have now been practically abandoned by all experts. The propeller is the next thing to be considered after the equilibrium has been secured, and a reliable motor worked out. Both Hargrave and Lilienthal gave preference to flapping vanes over the screw propeller, but other experimenters prefer screws. It is yet too soon to draw definite conclusions on this question, and it opens a field for further experimenting. In the author's opinion, we are now sufficiently advanced in the design of flying machines to perceive some of their limitations. They will be comparatively small and cranky, require much power, carry little extra weight, and depend for their effective speed on each journey whether they go against the wind or with it, so that they cannot compete with existing modes of transportation in cheapness or in carrying capacity. It is true that high speeds may be attained, and this may serve in war, in exploration, etc., but the loads will be very small, and the expense will be great.

Proposed Anglo-Italian Telegraph.—The want of direct telegraphic communication between Genoa and Milan, on the one hand, and London, on the other, has been felt for some considerable time, but although the question had been on the *tapis* for the past three or four years nothing definite was done. As the result of repeated representations from the British General Post Office, the Italian Administration are now moving in the matter, and we note that the proposal has been put before the Italian Parliament to establish two wires from Genoa and Milan respectively to the French border, by means of which telegraphic communication between Genoa and London and Milan and London could be maintained. Under the same Bill a credit of £2,000 for the construction of an international telephone line between Italy and Switzerland is also asked for. At present there is a telephone line in course of construction between Italy and France, and, if passed, the line between Italy and Switzerland will be the second international telephone in Italy. Reverting to the former proposal to establish a direct Anglo-Italian telegraphic communication, it is interesting to note that whilst in 1898 the number of telegrams which passed between Genoa and London hardly exceeded 230 a day, in 1900 this figure had reached 350 a day, and the messages between Milan and England now exceed an average of 260 per day. It is in consideration of these figures and the fact that the commercial relations between Genoa, Milan, and London are continually on the increase, that the Italian Government have agreed to put the proposal before Parliament.

Electricity in Nova Scotian Steelworks.—The cheapest iron and steel in the world is now said to be turned out from Canada's new iron and steel works at Sydney, Cape Breton, in Nova Scotia, and this is no doubt due in a great measure to the large part which electricity plays in the operations of the vast undertaking. According to the *Electrical World* of New York, electricity as a motive power is used in every conceivable form all over the steel plant. In the winter season, when ore and limestone are used from the stock piles, they are gathered up with scoop buckets worked from a trolley traveller, which delivers its load, two or three tons at a lift, into the bins by the furnaces. All the scooping and carrying is done by electric power. Three of the electrically-worked travellers serve four blast furnaces, up the sides of which the loaded buckets are hauled to a height of 85ft. by electric power also and dumped automatically into the furnaces. Nothing in the great plant bears an earlier date than 1900. Much of it will bear the date of 1901. It is typical of the latest and best that experience and practice of the great steel plants of Pennsylvania, Ohio, and Illinois have yet evolved, and it is only necessary to spend a couple of hours, it is said, about the first of the Sydney furnaces which have been put into blast to realise that the design of these modern plants, chiefly by the use of gravitation and electricity, have done away with nearly all of the hard, exposing

Digitized by Google

labour, and with much, if not all, of the smoke and fume which is associated with the making of pig metal at furnaces in Lancashire and Yorkshire in this country.

Canadian Electric Railways.—The electric roads in Canada are steadily increasing in number. According to the latest Government statistics, there were 35 electric railways in operation at the close of 1900. These aggregate 681 miles of track, an increase of 49 miles as compared with the previous year. Altogether these lines carried 118,129,862 passengers, which is equal to carrying every man, woman, and child in the country 21 times. The increase in this respect over the previous 12 months was 14,097,203, while the increase in the car mileage run was 1,277,508, the figure for 1900 standing at 30,924,355 miles. From this record it is shown that for each mile run there were 3·8 passengers carried in 1900 as against 3·5 in 1899. Some £4,126,600 of paid-up capital is invested in the electric railways in Canada, and the bonded debt amounts to about £2,523,884. For the 12 months under review the total receipts amounted to £1,084,508, and the expenses £653,600. As showing the great predominance of electric railways over steam in Canada, it may be mentioned that the passenger record for 1900 was a little over 87 per cent. by electric and a little under 13 per cent. by steam. On the steam railways the running expenses, also, were heavier than on the electric roads, the figures being 67·5 per cent. of gross earnings in respect of the former and 60·27 in the case of the electric railways.

Canadian Telegraphs and Telephones.—Some interesting information relating to the telegraphs and telephones in Canada has recently been published by the Board of Trade, which shows that the telegraph system of Canada comprises 3,906 miles of land and cable lines owned by the Dominion Government, and 30,717 miles in the hands of private companies. Thus the total number of telegraph lines is 34,623, and the wire mileage is put at 84,510. During the past five years the mileage of the lines under Government control has increased by 1,182 miles, and the total sum voted for construction, operation, and maintenance of telegraph lines last year was £105,480. An interesting point is that the messages of the signal, quarantine, and meteorological services, and also the bulletins giving the movements of the fish in the waters of the Gulf of St. Lawrence and other shore lines, are transmitted free of toll. Last year the company lines conveyed 4,960,414 messages. In 1891 the average number of messages carried annually per office was 1,700, and in 1900 it was 1,850, the number of offices increasing in the period by 198. Per mile of line the number of messages sent annually increased from 151 in 1891 to 161 in 1900. Turning to the telephone system in Canada, in 1900 there were 52,417 instruments in use, which is an increase of 18,917 over 1895. At the present time there are 38 companies in the Dominion carrying on a public telephone business, and these dispatched no less than 156,217,627 messages. While in 1895 the average was $5\frac{9}{10}$ messages per diem for each subscriber, the latest figures taken give an average of $8\frac{2}{10}$ messages, which speaks well for the progress made in this direction during the past five years.

The Overhead Trolley Wire Danger.—From Switzerland we hear of some particularly interesting experiments which a Swiss professor has been making on the question of the extent of injury which would result to a passenger on an electric tramway from coming into contact with the overhead trolley wire. The soles of the boots prove an effective obstruction to the passing of the current to earth, and, according to the report we have seen of the experiments, currents up to 800 volts had no effect upon the experimenter, even when grasping the wire tightly. When, however, the current came to 2,000 volts, the skin of the hand tended to burn when the wire was only lightly touched. These results were obtained when standing on moist gravel, but when the professor stood on clay covered with moist coal-dust, the effect of touching the wire is said to have been unbearable at a voltage of 1,000. The experimenter's conclusion, therefore, is that the voltage of overhead trolley wires should in no case exceed 1,000. The tests described above, however, do not meet the case of a passenger coming into contact with the wire while he holds a conducting medium, as, for instance, a brass rail, and accordingly the experiments were extended to ascertain the effect under such conditions, especially the effect on a workman who, with wet hands, might catch hold of two wires—one in each hand. The results obtained under these conditions were that at 10 volts a slight trembling was experienced in the finger muscles, while at 40 volts the whole arm was paralysed. With the hands dry the effects were not so serious, the dangerous voltage being put at 90. But, it is said, the difference between 80 and 90 volts was very pronounced. The experimenter estimates that while there is great danger from touching a trolley wire under these circumstances at 100 volts, death would result with a current of 240 volts.

Artificial Indiarubber.—A new process for making artificial indiarubber, emanating from France, appears in the *Electrical Review* of New York. We gather from this that the inventor mixes the fibre of ramie with the milky juice of a Chinese plant, known commercially in England as Pontianak gum. The synthesis of rubber is undertaken by the assimilation of gums and fibres of the same family which, under certain conditions, seem to have a natural affinity for one another and give an elastic material having the properties of rubber. The ramie fibre is, preferably, first dried, and the oily and volatile matters which it contains are removed. The gummy juice is then mixed with the fibre and the mixture crushed between cylinders heated to a temperature of 50deg. C. It is passed back and forward between these until the two constituents are completely incorporated in one another. The mass is then placed in an oven, the temperature of which is 150deg. C., and this temperature is raised gradually to a point between 175deg. and 205deg. After about four hours this process is completed. When the mass is cooled, it is seen that although the fibrous structure remains, its textile resistance is completely destroyed. The mixture is then worked at a temperature of 50deg. in a mixing mill until the fibrous structure is entirely destroyed and the mass is uniform. During this last treatment substances giving off oxygen, such as borate of manganese or permanganate of potassium, are introduced, to the proportion of from 5 to 8 per cent., and, if desired, a softening material, such as balata gum, up to about 10 per cent.; sulphur may also be added. This process being completed, the mass is allowed to cool for about 40 hours to permit thorough assimilation, and the mass is then cooked by steam under a pressure of 50lb. to the square inch for about three hours. When the product is cool it is said to have all the qualities of indiarubber. As the result of experiments it is stated that the following proportions give a good marketable quality of flexible rubber; gum, 80 per cent.; fibre, 15 per cent.; sulphur, 5 per cent.

Technical Education.—We are pleased to see Mr. Briscoe, principal of the West Ham Technical College, breaking a lance in support of that excellent institution. The *casus belli* was an article in the *Times*, in which it was said that there was no provision in West Ham for technical education. The writer might have known, as

Digitized by Google

Mr. Briscoe points out, that West Ham is not within the county of London, and, therefore, no report is made by the Technical Education Board of the London County Council as to the provision made there for technical education. West Ham is one of the county boroughs that has adopted the right policy of never allowing one penny of its receipts from the Custom and Excise duties to go in relief of the rates. These, on the contrary, were allowed to accumulate until the sum of £40,000 was available. Two loans of £35,000 and £23,000 respectively were raised on the security of the technical instruction rate, and this money was applied to the building and equipping of a technical school, which, Mr. Briscoe claims, is one of the best equipped in London, especially for the teaching of engineering and applied chemistry On the equipment of the engineering laboratories and workshops a sum of about £6,000 has been spent, and on the equipment of the chemical department a sum of about £2,000. At present there are something like 450 to 500 students attending the evening classes in civil, mechanical, and electrical engineering, of whom a fair proportion are doing work above matriculation standard. Provision is also made for the teaching of engineering and chemistry in the daytime, but this part of the work has not yet had a fair start, owing to the disastrous fire which occurred 18 months ago. We cannot emphasise too strongly the importance of allowing the unspent portion of the Custom, Excise duties, etc., to accumulate instead of applying it to the relief of the rates, and we agree with Mr. Briscoe that had London been content to do as West Ham has done in this matter, there would now be an unlooked-for sum of money—Mr. Briscoe puts it at over one million sterling—available for the further advancement of higher education in the Metropolis.

New Process of Sterilising Water.—The sterilisation of water is of ever-increasing importance, and many inventors have come forward in recent years with devices for the attainment of this object. It is only comparatively lately, however, that ozone has been used in the process. Messrs. Abraham and Marmier are the latest inventors to devise a method which is said to overcome the difficulty previously experienced of obtaining ozonised air in sufficient quantities. In the first place, air is ozonised in a specially-constructed air-tight chamber by means of a silent electric discharge. The electrodes are made of cast-iron hollow plates, and are hung side by side in this air-tight chamber in such a manner as to allow of plenty of air-space between them. The plates are isolated from one another by thick sheets of plate glass. Cool water is passed through the hollow electrodes so as to keep the chamber at the right temperature, and to prevent risk of a short-circuit. Further insulation is insured by causing the cooling water to enter the electrodes in drops and to leave in drops. A passage pierces all the electrodes but the last. Air is forced by means of a fan through an opening at one end of the chamber, circulates through the passage and around the electrodes, and leaves by a pipe at the other end in an ozonised condition. Only 2 or 3 per cent. of the oxygen of the air should be in the form of ozone, owing to the risk of forming oxides of nitrogen, which would render the water acid. The ozonised air is then forced up a tower, down which the water to be sterilised passes in the form of a spray. Recent experiments by this process in connection with the water supply of the town of Lille gave satisfactory results. Whereas Lille water usually contains from 1,000 to 4,000 organisms per cubic centimetre, after sterilisation by this process it showed only 60 to 100 non-pathogenic organisms per cubic centimetre. These trials, it is estimated, render it probable that water drawn from a river adjacent to a town, filtered by sand and then treated by this process, would cost much less than water conveyed from a spring or other source through mains over considerable distances. No reliable figures as to cost, however, have yet been obtained. In times of drought the use of such a process would undoubtedly prove of much value.

Electrical Plant on the "Deutschland."—A good description of the electric light and power installation on the steamship "Deutschland," one of the largest and fastest vessels of the many engaged in the Transatlantic traffic, appeared in a recent issue of the *Electrical World* of New York. The entire plant was designed and constructed by the Allgemeine Elektricitäts-Gesellschaft. Altogether there are some 550 incandescent lamps fitted in the different parts of the "Deutschland," while 23 electric motors are used for operating the various supplementary machines. Five steam dynamos are installed in this ship for generating the current, of which four are in the dynamo-room behind the main engine-rooms, and the fifth in a second smaller dynamo-room, which is likewise accessible from the main engine-room, but situated on the main deck above the water-level. The main circuit is composed of three principal parts—viz, what is known as the pilot lighting plant, comprising all the lamps that are required for service; the general lighting plant; and the plant for transmission of power. The circuits of the pilot lighting plant are fed from the switchboard in the upper dynamo-room, while the general lighting and the power circuits are fed from the main switchboard in the lower dynamo-room. Since the dynamos are not worked in parallel, they can be connected up in such a manner that any desired combination of circuits and dynamos can be obtained. The arrangements allow of any dynamo being readily substituted for another. The great advantage of such a system, especially on a big ocean-going liner like the "Deutschland," will be easily appreciated, as in the event of a breakdown in one part of the installation sufficient illumination could always be obtained from the other machines. Another point of interest is that wires provided with a strong seamless rubber insulation, and laid in impregnated wood casing, serve as main conductors in the remaining compartments. Where these conductors enter water-tight bulkheads, they are fixed in metal stuffing boxes mounted in the bulkhead. The power transmission plant of the "Deutschland" comprises 23 motors. From the drawings which appear in our contemporary we see that the motors are not inclosed. We think that for ship work, although the enclosed motor weighs heavier, it is really more advantageous in the long run. More than half of these 23 motors serve for driving fans for the ventilation of the different lower rooms of the vessel. Two of these ventilators, which are erected on the upper deck, provide for the fresh-air supply in the cabins of the engine drivers and stokers. Four other larger fans serve for ventilating part of the stokehold. The motors, the shafts of which are coupled directly to the shafts of the fans, are suspended from the ceiling of the boiler-rooms. Notwithstanding the coal dust, which is, of course, always present, and the unavoidable accumulation of moisture and dirt, the motors run constantly and quite satisfactorily without special attention or supervision. Besides various elevators for coal, provisions, mail bags, and the like, a kneading machine in the confectionery department is operated by a motor with worm gearing. The starting resistance is situated close to the motor. In the engine-rooms there are two electrically-driven drilling machines used for making small repairs during the voyage. A special set of men attend to the entire electrical apparatus on board under the supervision of two electrical engineers.

THE DIVISIBILITY OF ATOMS.

BY EDWIN EDSER, A.R.C.S., F.PH.S.

It may very reasonably be urged that the title of this article involves a contradiction in terms. If we define an atom as the smallest portion of a substance which could be produced by repeated divisions (*a, privative*; and *τεμνω, to cut*), it is clear that the expression "divisibility of an atom" implies the division of the indivisible. Nevertheless, experimental facts are stronger than human definitions or etymologies, and if we are forced to conclude that in certain circumstances atoms may be split up into simple components, we must revise our definition of an atom, rather than repudiate the inferences derived from experimental evidence. It is well, nevertheless, to remember that we are here brought very near to the boundary of human knowledge. Atoms and molecules have never been directly observed, and the inferences of their existence and qualities must to any thinking being range amongst the greatest triumphs of the scientific imagination. Cuvier inferred from the tooth of an unknown animal the structure of that animal down to the minutest details. But to infer the structure of an atom or molecule is even more difficult. A single drop of water comprises a number of molecules greater than the human mind can well grasp. Thus Lord Kelvin estimates that if a drop of water were magnified up to the size of the earth, the constituent molecules if magnified in the same proportion would probably be larger than ordinary shot, but smaller than cricket balls. The effects which we observe are the statistical results of the action and reactions of almost innumerable assemblages of molecules. From these effects, nevertheless, many properties of atoms and molecules may be inferred.

The proof of the existence of atoms rests ostensibly on the law, derived from chemical experiments, that if one element combines with another in different proportions to form several distinct compounds, the higher proportions are invariably simple multiples of the lower. Thus, in carbon dioxide, the ratio of the masses of oxygen and carbon is exactly double the ratio of the masses of the same elements in carbon monoxide. Dalton's explanation was that both these substances consist of molecules, each molecule of carbon dioxide comprising one atom of carbon and two of oxygen, whilst the molecules of carbon monoxide each comprise one atom of carbon and one of oxygen. The simplification effected in chemistry by the introduction of these ideas of atoms and molecules can scarcely be overestimated. The kinetic theory of gases, which gives a simple and fairly complete explanation of the physical properties of a gas in terms of the motions of its constituent molecules, gives further support to the molecular theory. Perhaps the best proof of the approximate truth of these theories lies in the number of researches which they have suggested, and which have led to the conclusions anticipated.

According to Prout's hypothesis, all the elements consist of combinations of different numbers of hydrogen atoms. This hypothesis was suggested by the fact that the various atomic weights were supposed to be exact multiples of the atomic weight of hydrogen. Thus, oxygen would consist of 16 atoms of hydrogen combined in some unknown manner. But research has shown that, taking the atomic weight of hydrogen as unity, the atomic weight of oxgen is not 16, but 15·96 (Meyer and Seubert). Hence the only evidence adduced in favour of Prout's hypothesis is found to be defective, and our only course is to abandon it. Moreover, no one has ever been able to convert one element into another.

In the kinetic theory of gases we generally begin by considering molecules to consist of perfectly elastic spheres. In doing this, it is realised that the structure of a molecule is really, in all probability, much more complicated. The spherical form is assumed as being that most easily dealt with mathematically. Various other kinds of atoms have also been assumed, as, for instance, Lord Kelvin's "vortex atoms." The vortex rings blown from a smoker's lips possess the property that the smoke forming one of them remains distinct from the surrounding air for a long time; in a frictionless fluid, a vortex ring would be indestructible, since the ultimate loss of form of a smoke ring is due entirely to friction. But the formation of a smoke ring is also due to friction. Hence a vortex ring in a frictionless fluid, such as we assume the ether to be, would be both uncreatable and indestructible by human agency. Such rings would, therefore, possess one property of atoms. Vortex rings can also rebound from each other, and exert attractive and repulsive forces on each other. The chief difficulty in regard to the vortex ring theory of atoms is to account for gravitation; this difficulty has never been completely overcome.

Turning from theories, we can gain valuable suggestions as to the structure of an atom from spectrum analysis. A particular element is not, as is sometimes stated, associated with one and only one spectrum. Thus nitrogen can be caused to give a spectrum consisting of a number of broad bands, termed flutings, these being found, by the aid of a powerful spectroscope, to consist of hundreds of fine bright lines arranged with a certain regularity. Under other conditions, nitrogen can be caused to give an entirely different spectrum, consisting of a comparatively small number of bright lines. No two elements give the same spectrum. To this fact we owe our knowledge of the chemical constitution of the sun and stars.

To each line in the spectrum of an element corresponds a certain definite wave-length of light radiated by that element. The waves of which this light consist are transmitted by the ether, and must have been produced, as disturbances of the ether, by the atoms of the element. Now, the velocity with which a molecule moves varies continuously with the temperature, and the shortness of the time elapsing between two collisions varies in a similar manner. Hence we cannot suppose that the lines in the spectrum (which are independent of the temperature of the element) are due to the motion of the molecule as a whole. Further, to account for the great number of bright lines found in some spectra (the spectrum of iron comprises over 500 lines) we are forced to assume a large number of different motions as the origin of the disturbance. We have no reason to suppose that the iron vapour in the electric arc consists of molecules comprising great numbers of atoms; hence we are forced to conclude that an atom itself comprises a large number of movable parts. When these parts are set in violent relative motion, each moving part produces a disturbance of the ether which results in the radiation of light of a certain wave-length. In recent years the bright line spectra of many elements have been decomposed into a limited number of "series" of lines. The characteristic of these series is, that the lines of which they are composed occur in a certain orderly succession. Thus the wave-lengths, λ, corresponding to a large number of the lines in the spectrum of hydrogen, can be found from the formula, due to Balmer,

$$\lambda = A \frac{m^2}{m^2 - 4}.$$

A is a constant determined by experiment. A succession of nine lines can be found by giving m the successive values, 3, 4, 5 . . . . . 11.

Our knowledge of these "series" is as yet limited. Further study in this direction may eventually lead to a great addition to our knowledge of the structure of atoms. For supposing that an atom consists of movable parts, if we know the law connecting the motions of these parts we can imagine a mechanical system of a similar nature. This aspect of atomic science is, however, as yet in its infancy.

Larmor has worked out mathematically a theory of atomic structure which is extremely suggestive. An atom is supposed to consist of a number of electrified particles revolving in orbits under the actions of their mutual attractions, just as the earth and the planets revolve round the sun. Thus an atom would consist, on a small scale, of a system of mutually attracting and repelling bodies greatly outrivalling the solar system in complexity of structure. Whether or not the ultimate constituents of any particular atom should be considered as common to all chemical elements, the distinctive characters of these latter resulting only from differences in the number and method of combination of the constituents, can hardly be settled at

Digitized by Google

present. Considering the fact that no one has ever as yet been able to transform one element into another, it would appear probable that the constituent particles of an atom have themselves distinctive characteristics.

A most important advance in our knowledge of atomic structure is marked by the discovery of Zeeman, that the spectrum of sodium, which normally consists of two bright lines in the yellow (the D lines), becomes modified when the source of radiation is placed between the poles of a powerful electromagnet. If a Bunsen flame, containing a strip of asbestos moistened with a solution of common salt, is placed between the poles of an electromagnet, each of the D lines is itself converted into a triplet, the distance between the central line and either of the outer components varying with the strength of the field in which the flame is burning. Further, the central line and the outer components are polarised. If the flame is viewed in a direction perpendicular to the lines of force of the magnet, then the central line and the two outside components are plane polarised, but in perpendicular directions. If, on the other hand, the flame is viewed along the direction of the lines of force of the magnet, then the central line is wanting, whilst the outside components are circularly polarised.

A simple explanation may be given of this interesting result. Let us suppose that each of the D lines in the spectrum of sodium is due to an etherial vibration, produced by the harmonic motion of a charged constituent of the sodium atom, the time of vibration, T, of one of these particles being connected with the wave-length, λ, of the resulting radiation, and the velocity of light, v, by the equation $\lambda = v\,T$.

The harmonic motion of a charged particle in any particular direction can be decomposed into two component vibrations, one parallel and the other perpendicular to the lines of force. Hence the resulting radiation can be explained as due to charged particles, some moving parallel and the rest moving perpendicularly to the lines of force. Further, a charged particle moving in any particular direction is equivalent to a small element of an electric current. Thus the magnetic field will produce no effect on the charged particles moving parallel to the lines of force, but will affect the motions of the particles vibrating perpendicularly to the lines of force. To understand the influence of the magnetic field on the motions of the latter particles, it must be remembered that a rectilinear harmonic motion is exactly equivalent to two circular motions, executed in opposite senses, in the same period as the original rectilinear vibration. Hence each particle vibrating perpendicularly to the lines of force can be replaced by two equal and similarly charged particles, revolving in circles in opposite directions round the lines of force.

Now it has been proved that a small charged body revolving in a circular orbit will behave, in a magnetic field, in a manner essentially similar to a small circular electric circuit, carrying a current equal in magnitude to the product of the charge into the velocity with which it is moving. Let us suppose that the lines of force of a magnetic field pass vertically downwards through the paper, and consider the action of this field on a positively-charged particle revolving in a clockwise direction in the plane of the paper. The magnetic lines of force due to the field will be in the same direction as the lines of force due to the electric circuit equivalent to the revolving charged particle. Hence, since an electric circuit always tends to embrace as many lines of force as possible, the diameter of the equivalent electric circuit will tend to increase, or the particle will revolve in a circle of greater radius than before. But the velocity of the charged particle will remain constant, so that it will complete a revolution in a period longer than T, its previous period of vibration.

Similarly, a positively-charged particle revolving in an anti-clockwise direction in the plane of the paper will be caused by the agency of the magnetic field to revolve with its previous velocity in a circle of smaller radius than before, so that it will complete a revolution in a time smaller than T. All particles revolving in the plane of the paper will produce etherial disturbances in the plane of the paper, the wave-length of the resulting light being proportional to the time of revolution of the particle. Hence, to an eye placed in the plane of the paper, the particles revolving in that plane will produce two distinct plane polarised rays—one of wave-length greater than the undisturbed wave-length, and the other less. This accounts for the two outer polarised components of either of the D lines, when the flame is viewed in a direction perpendicular to the lines of force.

A charged particle vibrating normally to the plane of the paper will be unaffected, since the lines of force due to the magnetic field are parallel to the path of the particle. Hence its time of vibration will be the same as without the magnetic field, and it will produce etherial vibrations perpendicular to the plane of the paper. This accounts for the central polarised component of one of the D lines, when the flame is viewed in a direction perpendicular to the lines of force.

When the flame is viewed parallel to the lines of force, no radiations will reach the eye from the particles vibrating parallel to the lines of force, since light consists only of transverse vibrations. This explains the absence of the central component under the conditions specified. The circularly polarised outer components are due to the particles revolving in opposite directions and unequal periods in the plane perpendicular to the lines of force.

The above results had been predicted by Lorentz from theoretical considerations before the performance of Zeeman's experiments.

The interest of Zeeman's discovery does not stop here. He was able to calculate the ratio m/q, where m is the mass of the charged particle and q is its charge. We know the value of this ratio in the case of electrolytic decomposition of a sodium salt. In this connection it is equal to the electro-chemical equivalent of sodium—*i.e.*, to $2{\cdot}4 \times 10^{-4}$. In the optical experiment, Zeeman found the ratio m/q to be equal to 10^{-7}, which is about $\frac{1}{1000}$ of the value obtained from electrolytic experiments. To explain this, the late Prof. Fitzgerald suggested that the part of the atom which carried the electric charge, and which, by its motion, produced the characteristic yellow light emitted by a sodium flame, is only one two-hundredth of the total mass of the sodium atom.

Thus we have obtained evidence that small parts of an atom, carrying electric charges, are capable of relative motion within the atom itself. We must now examine the evidence in favour of the theory that these charged particles can, under certain conditions, be forcibly torn away from the atom, and can exist by themselves for a limited time before they once more become absorbed in an atom.

Our evidence in this connection is mainly due to the researches of Prof. J. J. Thomson. Some suggestive evidence may, however, be obtained from the previous work of Lenard. Lenard experimented with a vacuum tube of special construction (represented in Fig. 1). T is a glass tube, closed at one end by a metal cap, C. In the centre of this cap is a small window, 1·7mm. in diameter, closed by a thin sheet of aluminium. A plane circular aluminium disc, K, acts as cathode, whilst a cylinder, A, acts as anode.

It was long ago proved that when a vacuum tube at sufficiently low pressure is connected to an induction coil, certain rays—named *cathode rays*—are emitted from the cathode. The effects observed can be best explained by supposing that these consist of streams of charged particles violently projected from the cathode. These rays produce phosphorescence if they strike against glass and some other substances. It is found that their path is deflected by a magnet placed near the tube, a fact which is explained consistently with the law previously mentioned, that a moving charged particle acts like an element of an electric current with respect to a magnetic field. When a sufficiently strong magnetic field is used, the rays form circles around the direction of the lines of force. When these rays strike against a piece of platinum the latter is heated. Further than this, the peculiar radiations discovered by Röntgen, and generally known as X-rays, are in certain circumstances emitted from substances which the cathode rays strike.

In Lenard's experiments the cathode rays strike against the small aluminium window in the metal cap of the tube.

Digitized by Google

In a dark room it is seen that faintly luminous rays radiate into the air from the aluminium window. These rays, named after Lenard, produce phosphorescence in many substances, and can be deflected by a magnet. This latter fact suggests that they consist of streams of charged particles. X-rays are not deflected by a magnet, and must, therefore, be explained otherwise. It was found that a positively or negatively charged body rapidly lost its charge when exposed to Lenard rays.

After proceeding a certain distance in the air, the Lenard rays apparently become absorbed; phosphorescence can only be produced within a certain limited distance from the aluminium window. Lenard found that the distance which they could travel was increased by rarefying the gas through which they passed. Using different gases it was found that the distance they could travel depended only on the density of the gas; thus hydrogen and oxygen produced the same absorption when the pressure of the oxygen was one-sixteenth of that of the hydrogen.

Lenard also found that the rays which he discovered could traverse thin layers of solid substances, such as aluminium, mica, glass, etc., the opacity of these substance varying to a very close approximation simply with their densities.

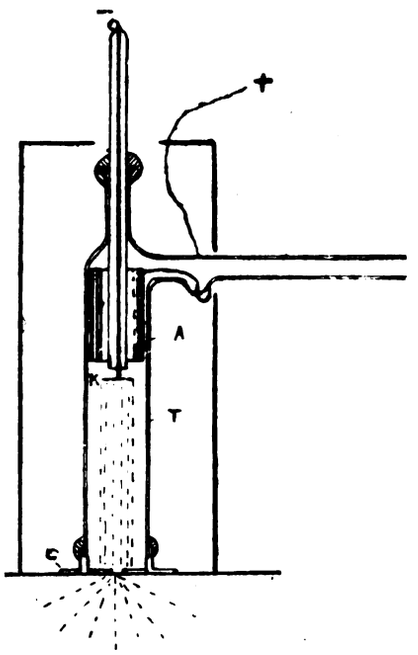

FIG. 1.

The simplest explanation of Lenard rays appears to be that they are cathode rays which have traversed the thin aluminium window in the cap of the tube. The deflection of cathode and Lenard rays in a magnetic field can be explained only on the supposition that both consist of streams of charged particles moving with considerable velocities. The question now arises, are these charged particles atoms, or collections of atoms, or particles smaller than atoms?

If the charged particles were atoms, they would lose their velocities when passing through a gas in a distance comparable with the mean free path of the molecules of that gas. The mean free path in air at half an atmosphere pressure is of the order 2×10^{-5}cm. But Lenard found that the rays which he discovered could penetrate to a distance of about ·5cm. in air at half an atmosphere pressure. Hence the atomic theory of Lenard rays must be abandoned. If the charged particles are larger than atoms, the distance which they could penetrate in a gas would be inversely proportional to the coefficient of viscosity of that gas, and this is independent of the density of the gas. But Lenard found the distance which the rays could traverse was inversely proportional to the density of the gas. Hence the charged particles cannot be larger than atoms.

The remaining alternative is that the charged particles are smaller than atoms. The comparative transparency of solids to these particles can be explained by assuming that they can actually traverse an atom, slipping in between the particles which, on Larmor's hypothesis, compose an atom, just as a comet can pass between the planets revolving around the sun.

Prof. J. J. Thomson has attacked the problem from other points of view. As already remarked, cathode rays can be caused to move in a circle around the lines of force of a magnetic field. In this case the centrifugal force due to the velocity with which the particle is moving, must be just balanced by the central force exercised by the magnetic field on the moving charge.

Let m = the mass of the particle;
" v = the velocity of the particle;
" r = the radius of the circle in which it moves.

Then the centrifugal force $= \frac{m v^2}{r}$.

A magnetic field, H, will exert a force of $H q v$ on a charge, q (in electromagnetic units), moving with a velocity, v. Hence

$$\frac{m v^2}{r} = H q v. \quad \therefore \frac{m v}{q} = H r \quad . \quad . \quad . \quad . \quad (1)$$

The value of H was known, and r, the radius of the circular path of the cathode rays, was observed.

Prof. J. J. Thomson then allowed the cathode rays to pass through a small aperture into a metal cylinder placed in the vacuum tube. After passing through this aperture they struck against a thermo-junction, which became heated. The rise of temperature of the thermo-junction was observed, and the water equivalent of the latter being known the heat produced became known, and from this the kinetic energy, E, of the moving particles entering the cylinder was calculated. Let us suppose that n particles entered the cylinder during the experiment, and were brought to rest on striking against the thermo-junction. Then,

$$\tfrac{1}{2} n m v^2 = E \quad . \quad . \quad . \quad . \quad . \quad (2)$$

From (1) $$\frac{m^2 v^2}{q^2} = H^2 r^2 \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Dividing (3) by (2) we get:

$$\frac{2 m}{n q^2} = \frac{H^2 r^2}{E},$$

$$\therefore \frac{m}{q} = \frac{n q H^2 r^2}{2 E}.$$

But $n q$ is equal to the charge which entered the cylinder during the experiment. This was determined by observing the rise of potential of the cylinder, which was connected to a condenser of known capacity. Let $n q = Q$.

Then, $$\frac{m}{q} = \frac{Q H^2 r^2}{2 E}.$$

In a particular experiment,

$Q = 2{\cdot}4 \times 10^{-6}$ electromagnetic units of electricity;
$E = 6{\cdot}3 \times 10^{5}$ ergs.

r, the radius of curvature of the rays in a field, H, of 35 units, was equal to 9cm. $\therefore H r = 315$.

$$\therefore \frac{m}{q} = \tfrac{1}{2} \cdot \frac{2{\cdot}4 \times 10^{-6} \times (315)^2}{6{\cdot}3 \times 10^{5}} = 2 \times 10^{-7}.$$

This value of m/q is of the same order of magnitude as was found by Zeeman. The value of m/q was found to be independent of the nature of the residual gas in the vacuum tube. If we suppose the charge, q, on one of the charged particles to be equal to the charge usually associated with an atom, then the mass of the charged particle would be equal to about $\frac{1}{500}$ of the mass of the atom. Another explanation might, however, be given by assuming the particles to be atoms, each carrying a charge about 500 times as great as the normal atomic charge. To obtain further evidence on this point, Prof. J. J. Thomson attacked the problem from another standpoint.

It was found by Hertz, in the course of his classical experiments on electromagnetic waves, that ultra-violet light falling on the spark-gap of his radiator induced a spark

Digitized by Google

when the potential difference between the knobs was insufficient to produce a spark otherwise. It was also found that ultra-violet light, falling on an insulated body carrying a negative charge, caused the leakage of that charge. Various explanations might be proposed to account for this fact; one is that small particles of the body, carrying negative charges, are thrown off under the action of the ultra-violet light.

It had previously been proved by Aitken that a supersaturated vapour is unable to condense into a mist, unless fine particles are present to act as nuclei for the condensing vapour. Thus the production of a fog depends on the presence of small particles floating in the atmosphere.

Hertz found that if the negatively-charged body was surrounded by a supersaturated vapour, a mist was formed near the body immediately after ultra-violet light fell upon it and leakage of the charge had commenced. This result was considered to afford strong evidence that the leakage was really due to the projection of negatively-charged particles from the body.

But if charged particles are really projected from the negatively-charged body under the action of ultra-violet light, these particles should be deflected by a magnetic field. Prof. J. J. Thomson found this to actually be the case. A disc of zinc was negatively charged, and it was found that the rate of leakage under the action of ultra-violet light was greatly diminished when the disc was placed in a strong magnetic field, of which the lines of force were parallel to the disc. The cloud formed by the condensation of supersaturated vapour was in this case found to be confined to a narrow stratum near the disc. The charged particles projected normally from the disc were twisted round the lines of force, and thus prevented from moving far from the disc. The thickness of the stratum of cloud depended on the strength of the field. From observations of the actual thickness of this stratum, corresponding to a given magnetic field, a relation similar to equation (1) above was obtained.

Mr. C. T. R. Wilson had previously found that when a saturated vapour is suddenly caused to expand, a cloud is not formed unless foreign particles are present to act as nuclei round which condensation may occur.

Prof J. J. Thomson utilised this result as follows. He enclosed a negatively-charged zinc disc in a vessel, the space contained by which was saturated with aqueous vapour, and allowed ultra-violet light to fall on the disc. Negatively-charged particles were thrown off, as previously explained. On allowing the saturated vapour to expand, a cloud was formed. The total mass of the condensed vapour could be calculated from the temperature of the saturated vapour, and its initial and final volumes. Hence if the size of the minute drops of water were found, the number of drops formed could be calculated. If each drop was formed by the condensation of vapour round one of the charged particles, the number of these particles projected from the negatively-charged body in a given time, under the action of ultra-violet light, would be known. The total quantity of electricity which had leaked from the disc being known from the fall of potential of the disc, the charge on each particle could be determined.

The size of the small drops of water composing the cloud was estimated by observing the rate at which the cloud sank. Let R be the radius of a drop, V the velocity with which it sinks, μ the coefficient of viscosity of the medium in which the cloud is formed, and g the acceleration due to gravity.

Then $$V = \frac{2 g R^2}{9 \mu}$$

The charge, q, carried by each particle was thus found to be of the same order as the charge carried by the hydrogen atom in electrolysis. The value of $\frac{m}{q}$ was found to be of the same magnitude as in connection with the cathode rays. Hence it follows that the mass of each charged particle must be about $\frac{1}{1000}$ of the mass of the hydrogen atom.

The mass of the particle which carries the negative charge under the action of ultra-violet light was found to be independent of the nature of the substance from which the particle was projected.

There thus appears to be weighty evidence that particles can be split off from atoms, and can lead an independent existence for a limited time. These particles are apparently identical, from whatever atoms they may be derived. Concordant numerical results have been obtained, under conditions which were widely different. Thus, though the weight of evidence derived from a single experiment may be small, the whole series possess an importance which cannot be neglected in framing a theory of atomic structure. We may hope for still further light on this interesting subject from the future researches of Prof. J. J. Thomson.

MUNICIPAL ELECTRICAL ASSOCIATION.

Glasgow Congress.

(*Continued from page 904.*)

Bailie W. MACLAY, the convener of the Glasgow Corporation Electricity Committee, then read his paper on

Notes on Street-Lighting.

BY BAILIE W. MACLAY, CONVENER OF THE GLASGOW CORPORATION ELECTRICITY COMMITTEE.

At the present time, when the incandescent gaslight is being so prominently forced upon the public notice, it may not be out of place to offer this paper upon street electric lighting. One reads of statements being made by gas engineers and others interested in gas undertakings which might lead the innocent public to suppose that the days of electric lighting, at any rate for street purposes, are numbered. Perhaps, however, the public have by this time learned sufficient of the "gassy" nature of the statements which are apt to come from those who seem now at any rate to consider us serious competitors, not to place implicit trust in their statements. Whatever else electricity may have accomplished, there can be no doubt that since its advent in 1880 there has been a steady and even rapid improvement in the standard demanded for street illumination. Until electric light was first introduced experimentally into the city of London, the public were contented with ordinary gas-burners consuming two to four cubic feet per hour. Some of the lamps at important places contained groups of burners which shewed evidence of an attempt to give a better standard of illumination. It may be taken that these gas lights gave an average of from 8 c.p. to 16 c.p. each. When the contract for the experimental electric lighting of some of the main thoroughfares of the city of London terminated, and the street-lighting again reverted to gas, the amount of illumination which had sufficed in previous years was found to be absolutely unbearable in comparison with the electric light, to which the public had now grown accustomed, and larger gas-burners, and increased numbers of them, had to be fitted along all the routes which had been electrically lighted. Even this improvement, however, was not considered satisfactory, and in due time electric arc lighting was reinstated along all the principal routes of the city of London. It is doubtless true that at the time these operations were carried out the incandescent gas mantle had not reached its present stage of perfection, but until electricity had forced the pace there seemed to be no serious demand for a higher standard of illumination at all. To-day, however, the public perpetually cry for more light in their streets, and the statement has appeared in one of our Glasgow evening newspapers that if there is one thing over and above pure water and effective sanitation which is absolutely necessary in a large city, it is efficient public lighting, and to offer bad lighting in order to save money is to waste both. Even supposing electricity had done nothing more than prove the immense advantage of properly lighted streets, it must be admitted on all hands that in that point alone it has served an extremely useful purpose.

Although electricity has been content up to the present to smile good-naturedly upon the laboured enthusiasm which it sees its elder sister displaying with regard to the incandescent gas mantle, in her attempt to get somewhere near her younger rival in the matter of efficient street-lighting, it may be well not to remain too long silent lest it should be thought that in reality the end of the street electric lighting was already in view. Everyone will admit the enormous improvement which is made by substituting incandescent gas mantles for the ordinary flat plain burner, at any rate, while the mantles are new, and during the prevalence of calm, fair weather, and it is hoped that the extra expenses, which will doubtless fall to be borne by the ratepayers, in regard to the renewal and up-keep of mantles and other accessories of the improved system, together with the extra time required to light

Digitized by Google

lamps not fitted with by-passes as compared with the older arrangement, will be cheerfully borne without a murmur in consideration of the improved illumination. There is nothing, however, in all this to show that for main thoroughfares, where a really brilliant illumination is desired, incandescent gas can in any way equal, far less surpass, electric light. A great deal has been made of the argument that electric lighting is "patchy," giving a brilliant illumination within a certain radius from the lamp and a comparatively poor illumination at points midway between, and great efforts have been made to show that by converting the ordinary flat-flame gas lamps into incandescent mantle lights, the illumination is much more evenly distributed although it may not be so intense at points near the lamps. This, however, has been investigated by electrical engineers, and it has been found that an equal standard of lighting measuring the light at points midway between the lamp columns cannot be obtained in this manner, except by using such a number of incandescent gas mantles that the cost will be more than that of electric lighting to give the same result. Apart from this, however, it is interesting to note that the gas people themselves are devoting their greatest energies to developing incandescent mantles, which they hope will give as large, concentrated, and brilliant a light as can be obtained from the electric arc. It would seem, therefore, that their anxiety in this direction goes entirely to disprove their own arguments.

On a recent occasion the question of lighting the Great Western-road, which may be styled the most fashionable promenade in Glasgow, was very prominently before the public, and was discussed very fully by the Town Council as well as by the sub-committee dealing with the matter. The question in this case was to some extent mixed up with that of lighting the tramway poles which had been fixed along the centre of the road at distances of about 40 yards apart. There was a very strong feeling amongst the public in favour of electric lighting, although incandescent gas lighting had been proceeded with along a considerable portion of the route and was showing a great improvement over the previous state of affairs. It was ultimately decided to do the lighting by means of electric lamps placed at a height of 27ft. from the road level to the centre of the arc, each lamp being constructed to take 7 or 7½ amperes and to give about 700 c.p. Counter proposals were made that gas mantles should be placed upon the tramway poles, but even supposing that the vibration of the poles did not have disastrous effects upon the mantles, it was found impossible to produce an equal standard of illumination at any reasonable cost in this manner, except by introducing side lamps at intermediate points, and even then it was found that the cost for the same amount of illumination at the darkest points would be greater with gas than with electric light. In every case full benefit was given to the incandescent gas mantle, as it was credited with 50 c.p. per mantle, this being a figure which doubtless may be obtained at the first start, but which public experience goes to prove is not maintained for very long. Of course, no variations occur with electric arc lights due to the deterioration of the illuminants, and provided the supply of current remains the same the light is the same, year in, year out.

Probably a point which has to some extent escaped notice is the fact that lights placed high up give a much more pleasing effect than when fixed low down, even though the illumination may be uneven. It is possible that a very even illumination might be gained with a large number of closely spaced lamps of low candle-power placed low down, but the effect would also be depressing in the same way that the lighting of a large hall is depressing unless the illumination extends to some extent upwards as well as downwards, or, more correctly, unless the whole cubic contents of the hall are illuminated. In this way when walking along a large street or thoroughfare lighted with electric lamps at a considerable height, one feels a sense of airiness and magnitude which is missing if the lights are fixed low down.

It is not the object of this paper to discuss in any way the question of comparative costs, but it may be well to state that the seven-ampere lamps before referred to will be charged for at the rate of £12 per lamp per annum, every lamp burning the whole night through. This charge includes the maintenance of the lamps, supply of carbons, trimming, cleaning, and the supply of current, but the capital expenditure, except so far as the mains are concerned, is borne by the police department, and is not provided for in these charges. Gas has been taken at the present price of 2s. 6d. per 1,000 cubic feet, and what is known as the ordinary 50-c.p. mantle has been allowed its fullest efficiency, which, in the author's opinion, is considerably more than it is entitled to. The prices which will prevail in Glasgow next year for 10-ampere arc lamps under similar conditions to the above will be £14 per lamp per annum. So far it would seem that incandescent gas lighting in streets is not unlikely to have the same result as it has had in house lighting. It has been observed by those in a position to know best that the ordinary consumer of electric light goes through three stages: (1) ordinary gas, (2) incandescent gas, and (3) electric light; and for this reason electricity supply authorities cannot but welcome the improvement over ordinary gas which the gas mantle promises. No one who has used incandescent gas is satisfied to go back to ordinary gas, and when thoroughly sick of incandescent gas the final plunge is taken into electric light, from which no one ever goes back. We may, therefore, take it that street-lighting is now entering upon the second stage, from which the only possible development must be an upward one—*i.e.*, into electric light. In other words, the incandescent gas mantle is now acting in a similar manner towards electricity to that in which electricity itself acted towards gas in 1880.

Extract from the "Gas World," March 16, 1901.

THE LIGHTING OF THE MEAN STREETS.

I desire to take this opportunity for urging the acceptance by the responsible authorities of a higher standard for the lighting of the streets of London—not only at show places and centres of traffic, although that is needed, but also, and especially, in the unornamental, thickly-populated quarters where the poor live. The people have a right to this better service. Think of the proportion of their income spent for lodging, and consider what they get for it. Let the humble streets be brightened, and the result will be something positive done towards that humanising of the town which is the cause that lies at the back of the plea for the better housing of the people. The gas lamp has long been called the policeman's best ally; but I wish to put its reputation higher than that. Above the prevention of crime and the facilitation of the arrest of the criminal is the cheering influence of good light, and plenty of it, on the moral and social sides of the people's life. I believe that personal smartness, cleanliness of body and surroundings, good temper, and harmless gaiety, are promoted by ample public lighting; and we want to see British people enjoy more of this boon than has hitherto been vouchsafed to them. If our climate is sometimes dull and depressing our gas is cheap and brilliant; wherefore let this British speciality be set off against the other. This can be easily done if the proper authorities will only rise to the occasion and put their minds to the work. The means are all ready to hand. To improve the public lighting of any locality that might be named would only be an affair of a week or two. Local authorities have frequently shown a remarkable twist in this connection. While heedless of the means at their disposal, they have readily increased their public lighting bill three or four fold for the purpose of stringing a few electric lamps sparsely along some chosen main thoroughfare. This is unjust to the mass of ratepayers who do not live in the favoured spots, and they are further injured by the extravagance of their representatives, in that it deprives them of all chance of getting good lighting for the back settlements and mean streets, which need it most.

Bailie MACKENZIE, of Edinburgh, opened the discussion, and expressed himself as being generally in agreement with the author. He did not, however, approve of the aggressive criticism of the gas undertakings which the author had given, as two departments of a corporation should not be at variance. He believed that unless they were prepared to pay three times as much for street-lighting by electric as for gas lighting, they should not convert from one to the other. In his opinion, the main routes should be electrically lighted, but he did not advocate electric light for side and unimportant streets. Thus with arc lamps, say, 40 yards apart it cost about £500 per mile to light streets with arc lamps. In Edinburgh they had had good experience of the effect of street-lighting. The hotel owner in Princes-street, with other gentlemen, had tried to get the electric lighting of the city into their own hands, and being unsuccessful, declined to take the light when the municipal supply was started. The arc lighting of that street made these gentlemen's premises seem so dark that now all were consumers.

Alderman PEARSON, of Bristol, was also substantially in agreement with the author. They in Bristol had competed so strongly with the gas company that the price of gas lighting for the streets had been reduced to a very low figure. Thus indirectly they had ensured a better and cheaper light for the side streets at what, he believed, was less than cost price. He believed that they slowly educated the public from the old batswing burner to the incandescent gas, and hence to the arc lamp.

Mr. C. H. WORDINGHAM believed that arc lighting for the main streets was an essential. In the side streets incandescent gas lamps were formidable rivals to the incandescent electric, but the public would, he thought, in the long run judge in favour of electric street-lighting. At first people

Digitized by Google

were apt to judge by the apparent brightness of the row of lights in view, but the proper way to value street-lighting was to look at the roadway. The claims for new gas lamps were extravagant, and in some cases the mantle used was not at all serviceable. He did not hold with placing the lamps too high, as then vertical surfaces were not then well lighted.

Dr. ALLFREY, of Hastings, said he was interested in both systems of lighting. The gas company were extremely active at Hastings, and they had installed incandescent gas in the side streets. The main streets were lighted with arc lamps, and the gas engineer had told him that he had used 100-c.p gas-burner to get a good comparative effect. They paid for public lighting on the same scale as for private supply—*i.e*, 10s. per lamp and 2d. per unit used. He did not believe in placing the lamp high up except in open spaces and at street crossings. Otherwise 15ft. to 20ft. was high enough.

Mr. HAYDN HARRISON did not agree with Mr. Wordingham respecting the light of arc lamps. The higher they were put, the better would be the distribution of light. In fact, an even distribution in candle-power feet was required. Vertical surfaces under one lamp would be lighted by the two adjacent lamps. In narrow streets and courts incandescent lamps should be used, and the light given out confined to the useful direction by condensers and reflectors. Although it was difficult to show on paper a commercial advantage for the electric incandescent over gas, it would be found on trial that the public preferred the electric system, as it was permanently better.

Bailie MACLAY, who had to leave to attend a council meeting, then replied briefly to the speakers up to this point. He was in favour of a keen competition between the electricity and gas departments of a corporation, but did not wish to be harsh on the gas industry. He was, in fact, a member of the Gas Committee of Glasgow. He thanked those who had taken part for letting him off so lightly.

Alderman RADFORD, of Plymouth, continuing the discussion, explained that in that town they had designed and erected their own incandescent gas lamps for the side streets. They paid the gas company 5 per cent. less than ordinary consumers. He thought that incandescent electric lamps for street work had yet to be much improved to compete with the Plymouth incandescent gas lamp, which only took 2½ cubic feet per hour.

Councillor ELVY ROBB, of Tunbridge Wells, deprecated the spirit of funk displayed by some speakers over incandescent electric lighting for streets. In his town they had found it to be a great success. The gas company offered a 50-c.p. incandescent burner for £3. 17s. 6d. per annum, while the Electricity Committee got the work at £3. 7s. 6d. for two 16-c.p. electric lamps per post. They had now the major portion of the street-lighting in their own hands.

Alderman BRUCE, of Sunderland, said that their Corporation did not own the gasworks. Some three years ago they started arc lighting the streets, and they so arranged the pillars in the main streets that the side streets were partially lighted too. They found 21ft. the best height for the lamps, and placed the same 60 yards apart. The better lighting increased the ratable value of these main streets, and this should be considered with the increased cost.

Alderman POTTER, of Taunton, referred to the bitter competition which the Taunton Gas Company had instituted to the municipal electrical undertaking. This had advertised this undertaking, and conduced to its success. He did not agree with Bailie Mackenzie's statement that electric street-lighting cost three times more than gas, as it could only be so if the gas lighting had been very poor and ineffective. It was not fair, for instance, to compare the present cost in Taunton of electric street-lighting with the cost of gas lighting the same streets by gas 10 years ago. In fact, a magistrate had once said that the safest place for a burglar to hide in Taunton 10 years ago was under a lighted gas lamp. They gave £3 per annum for their incandescent electric lamps as against £2. 17s. 6d. offered by the gas company. They had the permission of the Corporation to displace all gas lamps whenever they extend their electric mains, and this was always done. In spite of the low price of street-lighting, they had for the last two years returned to the Corporation the equivalent of a penny rate from the profits of the electricity department.

Bailie FINDLAY, of Glasgow, believed in a fair field and no favours, and letting the best system win. One great advantage of a gas company was that the engineer could write to the papers and be answered, which was better than a fight in the dark. They had not encouraged electric street-lighting in Glasgow as they should have done, but he hoped for more of it in future. When they put arc lights up along their first electric tramway there had been a marked decrease in crime. In Glasgow they never used any profits to reduce rates.

Mr. TREMLETT CARTER explained how the human eyes worked most efficiently with a uniform illumination.

Mr. E. E. HOADLEY, of Worcester, described the success they had secured in lighting courts and side streets with improved electric incandescent lamps.

Alderman IVEY, of West Ham, showed how unfair it was to light main streets with arc lamps at a low cost. This light improved the value of the shops at the expense of shopkeepers in side streets. He advocated a flat rate all round, rather than creating a preferential rate in favour of residents on main routes.

Mr. NEWINGTON, of Edinburgh, said they had replaced the gas lamps in the main streets by arcs. The cost of lighting had gone up from £3,200 to £11,000 per annum, but for the increased cost they got from 25 to 30 times more light. He thought £13 per lamp was the lowest possible charge per arc lamp when half were turned off at midnight. It cost them £13. 2s. last year at Edinburgh. At the price mentioned in the paper (£12), he thought the department would lose money.

Mr. W. A. CHAMEN explained that the electricity department had not to pay the capital charges on the lamps, which made a difference.

Mr. J. H. RIDER, the chief electrical engineer of the London County Council, then read his paper on

Uninsulated Returns in a Tramway System.

BY JOHN H RIDER, CHIEF ELECTRICAL ENGINEER, LONDON COUNTY COUNCIL TRAMWAYS

The general regulations prescribed by the Board of Trade, under the provisions of the Tramways Acts, include, amongst others, clauses which relate to the employment of uninsulated metallic return circuits of low resistance. Such returns, in the shape of the tramway rails, are up to the present in universal use in this country, and consequently the clauses mentioned are of universal application. It is provided that the uninsulated return shall be connected with the negative terminal of the generator, and that all parts of the return circuit which do not consist of the rails shall be insulated, unless of such cross-sectional area as will reduce the difference of potential between the ends of the uninsulated return below seven volts. This is also the maximum pressure allowed between the ends of the uninsulated return farthest from and nearest to the generating station.

Excepting, perhaps, that the maximum allowed is too high, no fault can be found with these requirements, as unless the differences of potential be kept low, excessive earth currents will flow, causing considerable damage to any metal pipes in the vicinity. The earth, being more or less a conductor, practically connects all buried metal near the track to the rails. Unless great care be taken, therefore, the return current leaks out from the rails and flows through any other metal which may be lying in the neighbourhood of the track. Being no respecter of paths, it has been even known to make use of the lead sheathing of the tramway feeders. The mere passage of the current through these irregular paths does no harm, but at all points where the current *leaves* the rails or the pipes or the sheathing, corrosion takes place by reason of electrolytic action. The number of places at which the current flows into or out of the rails or pipes, is entirely a question of relative resistances (or of conductivities) between the various paths open to the current, and at each place of leaving corrosion goes on. The only way to prevent leakage currents is to make the proper path of so low a resistance that the difference of potential between any two points is at all times exceedingly small. The requirements of the Board of Trade in this particular are most reasonable, and the engineer who thoroughly appreciates the position will endeavour to bring the maximum below this amount for other reasons than to comply with the regulation.

Digitized by Google

In the opinion of the writer, however, some of the other regulations are not only unnecessary, but even undesirable, as, for instance, those relating to the earthing of the negative 'bus bar. Regulation No. 5 says: "When any part of a return is uninsulated, it shall be connected with the negative terminal of the generator, and in such case the negative terminal of the generator shall also be directly connected, through the current indicator hereinafter mentioned, to two separate earth connections which shall be placed not less than 20 yards apart. Provided that in place of two such earth connections the corporation (or company) may make one connection to a main for water supply of not less than 3in. internal diameter, etc." Regulation No. 6 says: "When the return is partly or entirely uninsulated, the corporation (or company) shall in the construction and maintenance of the tramway (*a*) so separate the uninsulated return from the general mass of earth, and from any pipe in the vicinity; (*b*) so connect together the several lengths of the rails; (*c*) adopt such means for reducing the difference produced by the current between the potential of the uninsulated return at any one point, and the potential of the uninsulated return at any other point; and (*d*) so maintain the efficiency of the earth connections specified in the preceding regulation (No. 5) as to fulfil the following conditions—viz.: (1) that the current passing from the earth connections through the indicator to the generator shall not at any time exceed either two amperes per mile of single tramway line, or 5 per cent. of the total current output of the station; (2) that if at any time and at any place a test be made by connecting a galvanometer or other current indicator to the uninsulated return and to any pipe in the vicinity, it shall always be possible to reverse the direction of any current indicated by interposing a battery of three Leclanché cells connected in series if the direction of the current is from the return to the pipe, or by interposing one Leclanché cell if the direction of the current is from the pipe to the return. "In order to provide a continuous indication that the condition (1) is complied with, the corporation (or company) shall place in a conspicuous position a suitable, properly-connected, and correctly-marked current indicator, and shall keep it connected during the whole time the line is charged." Condition (2) is, of course, merely intended to show that the earth connection is maintained in good order.

It will be observed that the current coming back from the rails *vid* the earth to the negative 'bus bar must not exceed a certain value. The strength of this earth current will depend entirely upon two things: (1) the difference of potential between the rails and the negative 'bus bar, and (2) the resistance of the earth path. The former is the fall of pressure on the return feeder, which, although it may be only a small amount from the point of view of economy in transmission, may be enough to send a large current back through the earth, particularly if the resistance of the earth path be low. This may readily happen on account of the existence of water or gas pipes near the return feeder, and particularly when a water-pipe is used as the earth-plate at the generating station. In the case of the Plymouth electric tramways, where the shortest return feeder is 760 yards long, being connected to the rails at their nearest point to the generating station, the resistance between the rails and the earth-plate (water-pipe) is only about 0·5 ohm. It was found that 25 per cent. of the return current came back through the earth. Now the resistance of the earth path can be made practically infinite by the simple expedient of removing the earth connection from the negative 'bus bar.

Regulation No. 6 (1) is apparently intended to protect gas and water pipes by ensuring that no current (or only a very small amount) shall come back through the earth to the generators. Regulation No. 5 practically invites such current, and provides means for its measurement. If the earth connection be removed from the negative 'bus bar, no current can come back through the earth. Why then should the connection be made? The Board of Trade regulations appear to provide for an earth connection at the wrong place. When the return circuit of a tramway system consists partly of uninsulated rails and partly of insulated cables, the insulated part should be kept insulated except at the point where it joins the uninsulated part, and there the earth connections should be made rather than at the other end where it is joined to the negative 'bus bar. With more than one return feeder, negative boosters may be necessary to keep the points of earth connection at the rails at about the same potential. Earth currents would then be practically non-existent. With only one return feeder no negative booster would be needed, unless it were desired to reduce the fall of pressure for economical reasons. In this case it would depend entirely upon the length of the return feeder as to whether it would be better to add to its cross-section or to use a negative booster. In the majority of cases the latter would probably prove the better way.

If the ventilation of this subject by the Incorporated Municipal Electrical Association should result in a modification of the Board of Trade regulations, then this short paper will not have been written in vain.

At the conclusion of his paper, Mr. RIDER announced that the subject of it had practically been removed from the field of controversy by an alteration of the regulation of the Board of Trade. Mr. Trotter had written him on Friday last to say that the clause had been amended to read: "When the generator is at a considerable distance from the tramways, the uninsulated return shall be connected to the negative terminal of the generator by means of an insulated return conductor, and the generator shall have no other connection with earth; and in such case the end of the insulated return connected with the uninsulated return shall be connected also through a current indicator to two separate earth connections, or with the necessary consents to a main for water supply, or with the like consents to both in the manner prescribed in this regulation."

Mr. T. P. WILMSHURST, of Derby, said a similar case as that described had arisen at Halifax, where they earthed the junction of the insulated and the uninsulated return with the knowledge of the Board of Trade. Where many feeders were required, negative boosters were better. He did not agree that the seven-volt limit required lowering.

Mr. C. H. WORDINGHAM congratulated the author on his paper, and on his appointment with the London County Council. He thought it would be well to always keep down the drop below the seven-volt limit, so as to avoid all possible damage from electrolysis. It was absurd to cry out against a statement that damage might result.

Mr. J. F. C. SNELL, of Sunderland, said that they used an earth at the junction of negative feeder and tracks, and also a negative booster. This latter was on a return feeder, which could be connected to any desired part of the track. He had specified the track to have only half the Board of Trade limit of drop, and the contractors succeeded in obtaining such a low drop in the return, even at full load. He hoped that members would collect reliable records of the working of their return circuits for reference at a later date.

Mr. RUTHVEN MURRAY then read a letter from Mr. A. B. Bromley Holmes, of Liverpool, to the effect that the old regulation did not prevent a long connection from the negative pole to earth, and this connection might be the negative feeder.

Mr. MINSHALL, of Croydon, said he was arranging both + and − feeders of the same size, so that either could be used as the + feeder. He noticed that the Americans were adopting our seven-volt limit.

Mr. R. C. QUIN, of Blackpool, said that a 3½-volt drop in return feeders was quite possible. He also believed in bond pipes to the track near the earthing point.

Mr. TURNBULL, of Tynemouth, said he feared there would be electrolytic trouble at the joints of the pipes if they were connected as designed by Mr. Quin.

Mr. TREMLETT CARTER explained that the earth was a conductor, not an electrolyte, and that at seven volts electrolysis did not take place in consequence.

Mr. SAYERS did not agree that the earth could be considered as a homogeneous whole in the way suggested, as local conditions were so varied.

Mr. RIDER briefly replied, regretting that the discussion had been spoiled by the alteration of the Board of Trade regulations.

The members then adjourned to the City Chambers, where they were entertained to lunch by the Corporation of Glasgow. Lord Provost Chisholm presided, and among others present were the Mayor of York, Rev. Dr. Fergus Ferguson, Mr. W. A. Chamen (president of the association), the magistrates and members of the Coryoration, and over 200 others.

The loyal toasts having been given and duly honoured, the LORD PROVOST proposed "The Incorporated Municipal Electrical Association." Although the association was of comparatively recent date, it had grown marvellously, owing to the extension of electrical enterprise in connection with municipalities, and, he hoped, also to the growing sense of the importance of the enterprise, and to growing interest on the part of engineers and of municipalities in the development of municipal electrical

Digitized by Google

schemes. The objects for which the association existed were of a patriotic and public-spirited character, as it existed for the purpose of promoting, not the interests of those engaged in the respective undertakings, but the interests of the undertakings themselves. An association which tried to bring together and to unite for a common end interests which otherwise might be found running off at a tangent from each other, was entitled to their heartiest acknowledgements and to their best wishes for its success. The president of the association was their own electrical engineer, who had been brought from London, while Glasgow had sent Mr. Chamen's assistant to be electrical engineer at Brighton, a proof of the cosmopolitan character of electrical undertakings.

Mr. W. A. CHAMEN, in acknowledging the toast, said that the association was unique in its character, and might be called in some sense an experiment. They had tried to combine members and officials of town councils in one association in a way which, he thought, had not been attempted before. He dwelt upon the importance of their aims, and as showing the interest taken in the association he mentioned that they had 140 town councillors and 110 engineers present from all parts of the kingdom..

The LORD MAYOR OF YORK proposed "The Lord Provost and Corporation of Glasgow."

The LORD PROVOST, in responding, said that Glasgow had a very deep interest in the prosperity of municipal electrical enterprises. They had a larger number of these than any other city, having electric lighting, electric power, electric tramways, and telephones all under the management of the Corporation. The Glasgow Corporation had had an arduous struggle with successive Governments, lasting over a series of years, before they got power to instal a municipal telephone system. That power had now been obtained, the system was being established, and the only complaint was, not that they could not get a sufficient number of subscribers, but that they could not put their subscribers sufficiently quickly on the switchboard. The Corporation of Glasgow were thus greatly interested in the prosperity of municipal electrical undertakings, and had much reason to welcome to the city this congress, which sought to promote the excellence and the success of such undertakings.

The proceedings then terminated, and the members afterwards visited the following works: the Pinkston generating station of the Glasgow Corporation tramways department, the Dalhousie-street electric sub-station of the tramways department, and the Port Dundas generating station of the electricity department.

ANNUAL DINNER.

The annual dinner of the members of the association was held in the Windsor Hotel in the evening. The President, Mr. W. A. Chamen, occupied the chair. Altogether about 200 gentlemen attended. After the loyal toasts had been proposed and pledged,

Alderman PEARSON proposed "The Lord Provosts and Corporations of Glasgow and Edinburgh."

Lord Provost CHISHOLM, in replying, said the Corporation did not proceed upon the theory that it was their duty to municipalise everything. They proceeded upon these three general lines. If an article was in its production something like a practical monopoly, if it was at the same time something like a practical necessity, and if it required for its production and distribution the use of the streets of the city, then the Corporation held that it ought to be under their management, and they did not rest satisfied till they got it.

Mr. NEWINGTON (Edinburgh) also replied to the toast.

Mr. T. P. WILMHURST proposed "Scientific Institutions."

Dr. MAGNUS MACLEAN and Mr. WM. FOULIS acknowledged the toast.

Lord Provost CHISHOLM afterwards proposed "The Incorporated Municipal Electrical Assocation," and said, while emphasising the friendly relations between the electricity and gas departments in Glasgow, he would like electricians to understand that there was a veritable and real competition between gas and electricity. He illustrated his contention by reference to the display of gas lighting in the grounds of the exhibition.

The CHAIRMAN, in his reply, said that he had not the faintest doubt that everything which had been recently achieved in the way of incandescent gas lighting could be equally achieved in due time with electric lighting.

Other toasts followed.

THURSDAY, JUNE 20.

On Thursday, 20th, the members of the above association and the visitors attending the convention left Glasgow by the 8.45 train for Edinburgh. The meeting to discuss papers was held in the Freemasons' Hall, where Bailie MACKENZIE, the convener of the Edinburgh Electricity Committee, welcomed the members in the absence of the Lord Provost. In a short speech he referred to the capture of Glasgow by the Americans, and, in passing, expressed his opinion that the present tramway system with its overhead equipment was only a temporary makeshift. The Edinburgh electricity supply was having a hard fight to keep up with that of the Glasgow Corporation, but they were not handicapped in the first instance by having to buy out an electric light company. They had in Edinburgh some 570,000 equivalent 8-c.p. lamps connected, while of that there were some 2,100 h.p. of motors. They had a flat rate of 3½d. for light and 1½d. for power, which at least was comprehensible. Bailie Mackenzie proceeded to chaff the president on the Glasgow system of charging, saying that few could understand it. One case had actually occurred in which a consumer with an annual bill of £22 could have reduced it to £18 by taking twice the quantity of energy. He heartily welcomed the association to Edinburgh, and hoped that the weather would be at least as good as that in Glasgow the day before.

The PRESIDENT (Mr. W. A. CHAMEN) thanked the bailie for his kind welcome, and complimented him on the success of the Edinburgh electricity undertaking. The curious case he had quoted against the Glasgow system of charging would not occur again, as the new rates in force made a distinction between energy supplied for light and that required for power.

In the absence of Mr. Fell the following paper was read first:

The Equitable Allocation of Costs in Combined Lighting and Traction Stations.

BY W. H. TITTENSOR, ELECTRICAL ENGINEER, DUNDEE CORPORATION.

In bringing this subject before the association, the author feels that the present time and place are particularly suitable for its consideration and discussion. Owing to the rapid development of municipal enterprise in this country within recent years, local authorities, duly armed with the necessary (and in some cases unnecessary) powers, find themselves, as undertakers, face to face with problems upon the proper solution of which the degree of commercial success attending a given undertaking may depend.

The question as to whether power for traction should be generated by a combined lighting and power plant or in a station specially erected and fitted up with plant for that purpose alone, is one of these problems, and it is the one perhaps which at the present moment is most urgently in need of the attention alike of the local authority and the electrical engineer. The two modes of procedure generally adopted in such a case are neither of them quite without more or less serious objections. (1) The outside expert, carefully formed as his opinion may be, is liable to be biassed by the "personal element," and this may be responsible to a great extent for the expert's decision in favour of a separate decision. (2) In the case of the resident engineer responsible for the running of the lighting station, the personal element together with a better load factor, larger plant and correspondingly increased allocations to management expenses, may influence his decision in favour of a combined station. In view of these facts it is hardly to be wondered at that local authorities find it difficult to decide which is the better course to adopt.

The author feels that in such cases the ultimate decision is too often due to the engineer's point of view being unduly emphasised, at the expense of the commercial and purely business aspect of the question. Many successful engineering schemes will not bear to be thus looked at, and yet it is undoubtedly the standpoint from which all such questions should be determined. If a local authority were asking for a supply either of electrical energy or of any other commodity

Digitized by Google

from two or more outside companies, it would, without hesitation, decide to buy from the cheaper source. The questions that the undertakers have to decide, therefore, are: (1) Can the combined station *generate* as cheaply as the separate station? and (2) which of these two stations can *supply* at the cheaper rate? The first question is one that any qualified adviser *with a knowledge of local conditions* can advise upon and be able to produce facts and figures to support his conclusions. The second question is one that many people would naturally expect to be dependent upon the first, but such is by no means the case, since that unknown element, "policy," has to be reckoned with.

Many people look upon an electric tramways undertaking owned by a local authority as a veritable "municipal Klondyke." If it leak out that the committee which is to be responsible for the running of the future combined station (generally the Lighting Committee) takes this view, even in a modified form, then unfortunately there is every liklihood that the Tramways Committee will put down its own generating plant. The author has always held that supplies of a *purely public nature* should be given at *cost price*. Under this head would be included, for example: (1) public street-lighting; (2) sewage pumping; (3) tramways, etc. On the other hand, however, no public works or department should be run on the lines of a "philanthropic institution."

The particular question dealt with in this paper is the cost of generation in a combined station. When the existing station is provided with *suitable plant*, and the "centre of gravity" of the lighting and traction systems coincide, the cost of generation should be cheaper in a combined station than in a separate station, *if the costs are equitably allocated*. These should be in proportion to the plant used for tramway purposes, and not according to the total output of the station for both lighting and traction; or, in other words, the costs should be allocated on the basis of the maximum demand upon the plant only used for supplying the tramways and not on the whole of the generating plant in the station. The traction department should be treated as an individual consumer, and supplied at a rate proportionate to the cost of generating the power required. Treated in this manner, the tramways are in an unique position, inasmuch as their maximum demand can be pretty accurately foretold and provided for. On the other hand, the cost of supplying a lighting system, spread over some hundreds of consumers with a variable maximum demand, must necessarily be greater than the cost of supply to a traction system.

The method adopted for determining the *selling price* of current to consumers supplied on the maximum demand system is pretty generally understood, and has been fully described and discussed elsewhere. The method of arriving at the *cost of generation* may, however, be dealt with on simpler lines, owing to the fact that in most stations the plant capacity is, or should be, well in excess of the actual maximum demand at any one time, in order to provide against interruption to the supply arising from breakdowns. The cost of "generating" and "supplying" electrical energy constitute two separate and distinct problems, and as such must be treated in accordance with attendant circumstances. In a given station the total standing charges will be the same, whatever the number of consumers connected may be or their total maximum kilowatt demand on the plant, but the cost of generation will vary in inverse ratio to the *number of* UNITS *generated*, and it is unnecessary to take into consideration the maximum kilowatt demand in determining the cost per unit generated. It is, however, necessary in "supplying" individual consumers to differentiate in accordance with their maximum kilowatt demands, in order to arrive at the cost per unit delivered at their terminals.

In considering the present subject, the author deals only with the *cost of generation per unit*, and in order to state the case more clearly an example will be given of a station just commencing operations. One of the first questions asked will be, "What number of units must be generated and sold at the maximum rate charged in order to meet expenses?" To determine this, we will assume that cost of generation = standing + running charges; then let x = number of units which must be sold at the maximum price in order to equal standing + running charges.

a = the maximum price per unit *in pence*;
b = the "running" cost per unit *in pence*;
c = the total "standing" charges *in pence*.

Then $$x = \frac{c}{a-b}.$$

Example.—The standing charges (c) in a particular station were £1,052. 8s. 2d. per annum; the running charges (b) were ·435d. per unit; the maximum price (a) to be charged was 2d. per unit. Then

$$x = \frac{252{,}578}{2\text{d.} - 0{\cdot}435\text{d.}} = 161{,}391 \text{ units.}$$

Therefore, it is necessary *in this particular case* to sell 161,391 units per annum before all expenses are met, after which each unit will cost 0·435d. The station referred to has an annual output of 322,782 units, therefore the total cost per unit generated would be

$$\frac{252{,}578}{322{,}782} + 0{\cdot}435 = 1{\cdot}217 \text{ pence.}$$

It is generally understood that the total cost is divided into standing charges and running charges, and in order to arrive at the relative cost of generating electrical energy for lighting and tramway purposes respectively, it is necessary to remember that the standing charges allocated to the tramways as a consumer are not affected by the actual maximum demand at any one time on the plant, but are dependent upon the total plant capacity *installed for tramway purposes only*. This is owing to the fact that up to the present it has not been found advisable to run tramways and lighting simultaneously from the same generators.

Taking as an example a combined station supplying both lighting and traction, it will be found that certain plant is set aside and used for tramway work only, and it does not matter, therefore, what the load factor may be, the standing charges on such plant will be constant. In determining the cost of generation, the crux of the matter lies in the allocation of costs. For the purpose of comparison the following headings will be used: *Standing Charges.*—Interest; sinking fund; management expenses; insurance; rents, rates; wages. *Running Charges.*—Fuel; oil, etc.; repairs.

Dealing with these headings singly, the amount allocated to the tramways account under each item should be determined on the following lines.

STANDING CHARGES.

(*a*) *Interest and Sinking Fund.*—Charged on the full value of the plant and apparatus in use. Charged on one half of the value of the stand-by plant required and available for lighting purposes also. (*b*) *Management Expenses.*—Charged in proportion to the value of the plant included in the above and inclusive of clerical expenses actually involved. (*c*) *Insurance.*—Charged in proportion to the value of the plant (*a*). (*d*) *Rents, Rates, etc.*—Charged in proportion to the ground space occupied by plant included in (*a*). (*e*) *Wages.*—Charged in accordance with the actual proportion paid to fireman, drivers, and attendants required on each shift during the hours that tramway plant is running.

RUNNING CHARGES.

(*f*) *Fuel.*—Charged on the actual fuel required for the running of the tramway plant. When steam is taken from a common bank of boilers, the cost of fuel per unit must not be obtained by dividing the total weight of fuel used by the total number of units generated; this would be unfair to the traction plant, for assuming that the latter is kept in proper repair, its efficiency will remain practically constant and the fuel consumption will vary but slightly, whereas in the case of the lighting plant the active stand-by losses vary considerably according to the lighting season of the year. By "active stand-by losses" is meant such losses as occur in the winter months, when boilers have to be kept banked for several hours per day in readiness for the peak of the load in the evening. In the author's opinion, it would be to the advantage of the traction plant to have its own boilers separate and entirely shut off from those of the lighting plant, as by this arrangement the proportionate consumption of fuel for traction could be ascertained without any difficulty. Where it is considered desirable, however, to have only one steaming plant for both traction and lighting, periodical tests of the efficiency of the traction plant should be made, when the actual fuel consumption per unit can be ascertained and apportioned accordingly. (*g*) *Oil, etc.*—Charged on the actual quantity used on the plant in operation. (*h*) *Repairs.*—Charged in accordance with the actual material used plus the cost of labour (as shown on time-sheets) necessary to maintain the plant in good order.

As an illustration, let a combined station be taken as follows:

Annual output for lighting	835,000 units.
" " traction	500,000 "
Total output	1,335,000 "

Total capacity of plant, 1,300 kw. Maximum demand for traction purposes, 300 kw. Total capital spent on plant, buildings, etc., £63,662, or an average of £48·9 per kilowatt. The actual value of plant installed for tramway purposes was £15·6 per kilowatt (exclusive of mains and outdoor appliances). The total cost of generation was £11,125 per annum, made up as follows:

	£	s.	d.	d.		
Interest	1,401	15	0	= ·252	per unit generated	Standing charges.
Sinking fund	967	17	6	= ·174	"	
Management	912	5	0	= ·164	"	
Rents, taxes, &c.	1,223	15	0	= ·22	"	
Wages	912	5	0	= ·164	"	
	5,417	17	6	= ·974	"	or £4. 3s. 4d. per kilowatt installed.

Digitized by Google

Fuel, etc.	3,726	17	6	= ·67	,,	Running charges.
Oil, etc.	367	2	6	= ·066	,,	
Repairs	1,613	2	6	= ·29	,,	
Total	11,125	0	0	= 2·000	,,	

The cost of generating 500,000 units under these conditions for tramway purposes was

$$\frac{450,000}{500,000} + 1·026 = 0·9 + 1·026 = 1·926 \text{ pence per unit generated.}$$

Under these apparently most favourable circumstances, the tramway plant appears to be charged with a large portion of the capital and standing costs of the lighting plant, and actually earns a profit (£1,312. 10s. per annum), which is appropriated for lighting purposes, whereas if the costs are equitably allocated, the actual cost of generation will be as follows :

	£	s.	d.	d.		
Interest	210	12	0	= ·101	per unit generated	Standing charges.
Sinking fund	140	8	8	= ·067	,,	
Management	158	10	0	= ·076	,,	
Rent, taxes, etc.	219	0	0	= ·105	,,	
Wages	273	0	0	= ·131	,,	
	1 001	10	0	= ·480	,,	
Fuel, etc.	1,041	13	4	= ·5	,,	Running charges.
Oil, etc.	54	3	4	= ·026	,,	
Repairs	608	8	0	= ·29	,,	
	£2,705	14	8	= 1·296	,,	

In submitting the above figures, the author does not wish them to be regarded as model costs to be accepted as station records, as they would be proportionately lower in larger and better-equipped installations. They are, however, intended to illustrate the application of the principles enunciated in this paper to actual working conditions.

Having ascertained in a given case the actual cost of generation, the percentage of profit to be charged on the supply may then be determined. It would be well for those responsible for combined stations to see that the profit charged does not make the cost of the supply to the tramways undertaking too largely in excess of the amount for which the tramway people could generate their own current; or the chances are that this consumer will be lost to the station. In fact, the advocates of the combined station, if they are to successfully combat the counter proposals which are almost sure to be forthcoming from the tramways department, must be prepared to show that they can supply power for traction cheaper than it could be produced by a separate station. The author's contention is that this can be done and profitably. In the combined station economies are effected in management and attendance (especially in the earlier stages), as a better paid and more competent staff can be employed in one station than in two separate stations, sharing the same amount of work between them; the management can, of course, be more efficiently carried out for the same reason. The cost of buildings and stand-by plant will also be less, as the latter, being available for either lighting or traction, need not be installed to the same extent as would be necessary in two separate stations.

Although many resident engineers may not look favourably upon a proposal to supply current for *any* purpose practically at cost price and may recommend separate stations, because of the greater amount of "management" required by the latter arrangement and the consequently increased remuneration likely to accrue therefrom, local authorities can hardly be expected to accept such recommendations, if before doing so they analyse them from a commercial and business standpoint. In bringing forward this subject—and it is one of vital importance at the present time—the author has done so more with the object of gaining for it the benefits of criticism and broader experience than with a desire to lay down any hard-and-fast rules, which might require modifying in order to suit certain localities and conditions.

Mr. J. F. C. SNELL, of Sunderland, complimented the author on bringing such an important subject before the association. He agreed with much in the paper, but, again, there was much with which he did not agree. He deprecated the remarks of Mr. Tittensor on tramway experts, and believed that a much higher standard of professional probity existed than was inferred by the author. As regards combined works, he considered that these were almost always advisable. Of course, in such large towns as Glasgow the conditions were by their magnitude different from those with which most present had to deal, but even in Glasgow he believed there would have been a decided advantage gained from combining the two generating plants. With respect to the price to be charged to the tramway department for electrical energy, some undertakings had adopted a very low figure. Thus, Liverpool commenced supply to the tramways at ·9d., while a Midland town asked 1d. per unit. This latter price had now been raised. He did not consider that it was right to supply at cost price or under, as that was unfair to the rest of the undertaking. As regard the author's division of the stand-by plant charges, he did not think that one half of these was enough to charge to the tramways. Again, the management expenses should be spread equally over all the units generated. He agreed with the author on the rent question, but the rates would certainly not be levied on the space occupied by the respective plants. The figures given in the paper were, as a rule, too low. Thus tramway plant cost nearer £40 per kilowatt than £15. 6s., and he would like to know what the author included in this latter figure. The capital charge being taken too low resulted in erroneous figures for the cost per unit in standing charges. He had tried to ascertain by the author's method what they should charge in the case quoted, and found it would be about 2·73d. per unit with his corrected figures. Capital charges alone came out at 1·08d. On the Sunderland consumption of 1,330,000 units per annum, the cost per unit with the same method came out at 1¼d. per unit, but no depreciation was allowed for. This at 5 per cent. brought up the price to 1·7d., and with margins for coal and rates, which varied continually, they really should not charge less than 2d. The last paragraph of the paper he strongly repudiated and condemned.

Mr. S. E. FEDDEN, of Sheffield, advocated three or two phase plant for combined stations, and that all municipal electrical engineers should be exported to the Continent with a £100 cheque in their pockets, but he did not discuss the paper.

Mr. C. H. WORDINGHAM considered the subject one of vital importance. The author was right in his system of ascertaining the charges by the maximum demand system, but in detail he differed from some of his items. There should be some profit made on the tramway supply, as that department was a profit-earning one. It must be a most extraordinary case where it did not pay to combine the light and traction plants, and could only be due to exceptional conditions in the placing of one of the stations. He did not advocate, as did the author, two separate plants in the one station, but rather a common generation by three-phase plant with the load divided up in the rotaries. As regards details of cost a considerable part of the coal—*i.e.*, that required to keep the boilers heated up—was a standing charge, and certainly part of the wages bill should be considered as a running charge.

Mr. J. A. BELL, of Aberdeen, said that he was a near neighbour of Mr. Tittensor, and the townspeople of Aberdeen wanted to know why he did not supply the tramways at the same price as the Dundee tramways were charged. At Aberdeen they supplied at cost price as ascertained after the energy had been taken. The author's system was fairly equitable in principle, but wrong in detail. He thought they should be very careful not to supply below cost price. On the author's system, Aberdeen tramways would be charged more than at present for electricity. He would ask Mr. Tittensor to explain how in Dundee he could afford to supply at 1½d. per unit and to maintain the feeders and overhead work into the bargain.

Mr. G. H. CORRINGHAM said he had great faith in the maximum demand system, which gave equally reasonable and right results when applied to tramway loads as to lighting loads.

Mr. J. CHRISTIE, of Brighton, said that Mr. A. Wright was putting down a three-phase station in the outskirts of Brighton, from which both lighting and traction loads would be supplied. In the meanwhile, they had had to put in a new plant for the tramway supply in their present station. All consumers were treated alike in Brighton, being charged at the rate of 7d. per unit for the first hour's use per day of their maximum demand and 1d. per unit for all above this. In consideration of the tramway department supplying their own feeders, they had reduced the first charge to 5d. per unit. He thought that one-half of the standing charges could fairly be charged to the tramways.

Councillor SMITH, of Sunderland, as chairman of the Electricity Committee, hoped to get some advantage out of

Digitized by Google

the paper, but Mr. Snell had the ear of the Sunderland Council, and might prevail. He believed the supply was being given at cost price, and when the large new station was erected in Sunderland should like to take over the old works for the tramway load alone. In the early years of the undertaking the ratepayers had to make up a deficit, but now a profit was made it was hard to combat the idea that it was made from the tramway department.

Alderman BRUCE, the chairman of the Sunderland Electric Light Committee, said that when this question of charging the tramways for current first came up they had obtained a full report from Mr. Snell, who found that in certain towns interest and depreciation were not taken into account when fixing the price. There should be no difficulty in settling on a fair rate, but it was not right that the electric lighting department should supply at bare cost price so that the tramway department could show a huge profit. They were all working for the good of the townspeople, so that a profit did not hurt anyone.

Mr. R. A. CHATTOCK, of Bradford, referred to the circular letter on the subject of the paper which he had recently sent round to members of the association. He found when he went to Bradford that the tramways were supplied at 1d. per unit, and that that price meant a loss to the undertaking. They maintained the feeders for that figure. He had looked into the matter and found that the total cost of generation came out at 886d. per unit, the interest and sinking fund at ·671d., and depreciation at ·098d., making a total of 1·655d. per unit. He thought that a fixed price should not be made, but that the actual cost should be ascertained and charged. The cost of coal, etc., should be taken over the whole units supplied for power. It would very difficult to ascertain the percentage of coal to be put to standing charges.

Councillor IVEY, of West Ham, considered they could safely leave the allocation of cost to the electrical engineers. They had a combined committee in West Ham as well as a combined plant, and he believed in that. In fact, a one-man committee would be the most satisfactory of all.

Dr. PAXTON, of Bolton, said he had spent much paper and blacklead analysing the report of the Leeds tramway station. They supply 10 to 15 per cent. of their load for arc lighting at 5d. per unit, and hence claimed to produce the tramway units at ·6d. This figure was arrived at by deducting the arc lamp revenue from the total cost and then dividing by the units used on the tramways. At Bolton they charged 1½d., and he believed they made a profit.

Mr. R. C. QUIN, of Blackpool, had adopted the same method as the author when fixing the charges for energy to the Blackpool tramways some years ago, and found the results satisfactory. Up to 260,000 units per annum they charged 2d., and above that quantity 1¾d.

Councillor WORTHINGTON, of Wigan, said he was chairman of the combined Lighting and Tramway Committee, and he did not trouble at all on the matter. If they charged the tramways too much, it only meant that the money went from one pocket of the Corporation to another, and it did not affect the ratepayers a bit. In fact, just now, when the lighting load was not large enough to pay, they saved at least £200 a year in income tax by so doing.

Mr. TITTENSOR said he would reply in the *Proceedings*, adding that while figures never lied, l——s could figure.

Mr. A. L. C. Fell's paper on "Braking Apparatus for Electric Cars" was then taken as read. The following is the full text of the paper:

Braking Apparatus for Electric Cars.

BY A. L. C. FELL, TRAMWAY ENGINEER, SHEFFIELD CORPORATION.

The various methods of braking cars on electric tramways call for serious consideration owing to the comparatively high speed at which electric cars travel through crowded thoroughfares, and also that cars may be safely handled on steep gradients. On railways a fairly good rail can always be relied on, but in street tramway work the state of the rails is very unreliable. Car brakes may be classed under six different headings—viz. (1) hand brakes; (2) friction brakes; (3) slipper brakes; (4) pneumatic brakes; (5) electromagnetic brakes; (6) Newell electromagnetic brake.

Hand Brakes.—The best known of these is the link suspended type, the links being set at a slight angle so that gravity will tend to keep the shoes away from the wheels when they are not in operation. The shoe and head are usually of the well-known "Christie" pattern, the shoes being retained in the holders by means of a pin, which can be easily removed when the shoes require replacing. The brake beams and equalising brake beams are placed with their surfaces against each other, the power lever being the fulcrum at their centres. In the majority of cases the brake rods are made in one piece, thus avoiding unnecessary swivel joints. The link suspension is claimed to give much freer movement, as it does not become clogged with either mud or ice. In the writer's opinion, there is not any particular advantage to be gained by using one particular type as compared with another. The chief point in connection with all brakes is that reliable men should be employed to fit them on to the wheels of the cars, so as to ensure even pressure on the wheels. One very important matter concerning the adjustment of brake rods is not to employ locking nuts, as they cause serious delay when this work is necessary. The adjusting nut should be kept in position by a pivoted claw, which can be simply thrown back when it is necessary to move the nut. The writer has tested various types of brake shoes, and finds the "Corning" brake shoe is the best. This shoe, although somewhat more expensive in first cost, has been found to last several times the life of an ordinary cast-iron shoe without materially affecting the wear and tear on the wheels. The main body of the "Corning" shoe is of tough hard iron cast about a soft grey iron core. The body of the shoe has a chilled face. The combination of the chilled iron body and the soft iron inset makes the frictional quality almost equal to that of ordinary cast iron. The wearing qualities of this combination appear to give splendid results. A sample of one of these shoes is shown. This ran over 12,300 miles on a route where the gradients are very steep—viz., 1 in 11 and 1 in 12—and would easily have run another 1,000 miles before replacement would have been necessary. Ordinary hard cast-iron brake shoes on another car on the same route only ran for 6,000 miles before they were worn out. The difference in the diameters of the wheels under the two cars was inappreciable. Tests are now being made with various types of brake shoes on steel-tyred wheels, but at the time of writing comparative results cannot be given.

Friction Brakes.—On cable cars or on electric cars where only one motor is used, or where a broad gauge is in operation, a friction brake can be operated. This consists of a spool or boom upon which a chain is wound, the chain being attached to the brake lever and the spool or boom driven by two friction plates operated by the driver through the medium of a lever, a slight pressure on which applied by the hand or foot instantly applies a very effective brake. This type of brake acts very rapidly in the case of an emergency. It is simple in design, cheap to obtain and to operate, its only objection being the amount of room required to properly mount it on the axle. For this reason, on the majority of tramroads in this country, it could not be used.

Slipper Brakes.—This is the most useful type of brake at present in operation in England, and simply consists of wood blocks which are pressed down on to the rails by means o levers, as shown on Fig. 1. The levers are operated by means of a handwheel connected by a chain or worm gear at either end of the car. The operating handwheel is fixed on to a tube spindle, which is placed outside the solid hand-brake spindle. The two spindles are quite independent of one another, and separate ratchets and pawls are provided for locking them independently. It has been found in practice that it is advisable to design the slipper brake operating handwheel so that it is impossible to lift the car off the rails. The framework carrying the slipper-brake shafting, levers, and slides is fixed to the sides of the truck frames. On all gradients steeper than 1 in 20 it is advisable to use the slipper brake, and the best results have been obtained when the slipper brake is worked as an auxiliary to the hand or electric brake. On single lines with steep gradients the slipper brake is especially useful, as it not only retards the descending car, but also cleans the rails for the ascending cars.

Pneumatic Brakes.—On several systems in this country pneumatic brakes are fixed on the cars, but in the writer's opinion they are not satisfactory, since they are not always reliable. They require complicated and perfectly fitted mechanism to compress the air; the cost of maintenance is very high, and the conditions under which a street car has to work are unfavourable to success on account of the mud, dirt, and dust under the car. The air, which is compressed, has to be drawn in under very unfavourable conditions, and the dust rapidly cuts up the cylinder of the air-compressor. The difficulties in connection with driving the air-compressor, and keeping up a sufficient supply for frequent stoppages, are problems which have not yet been satisfactorily solved.

Electromagnetic Brakes.—One type of this brake consists of two cast-iron discs, one of which is fixed to the motor and has a coil of wire wrapped round it, the other is keyed to the axle,

Digitized by Google

The motors are used as generators and gradually short-circuited through a rheostat and the disc coil above mentioned. The discs are thus magnetised and braking action is produced from three causes: (1) retardation due to converting motors into generators by driving them from the car axles on practically short-circuit; (2) drag due to eddy currents which are set up in brake disc as it revolves in the intense magnetic field of the brake shoe; (3) the mechanical friction between the brake disc and shoe. As the braking effect is so rapid, great care has to be exercised not to magnetise the discs too quickly, otherwise the wheels will at once be skidded unless a very plentiful supply of sand is used. On a good rail this type of brake can be used for taking a car down a gradient of 1 in 11, but it is always safer to use a slipper brake in conjunction with the electric brake. In practice it has been found advantageous to bring the slipper brake into operation at the top of a gradient and fix it; the speed can then be regulated by the hand or electric brake. In the writer's opinion, the hand brake should never be used in conjunction with the electric brake, but if the former is in use, it should be released before the electric brake is applied.

The Newell Electromagnetic Brake.—This is arranged to act as a magnetic slipper brake, the slipper being made of cast iron and having coils wound round it. The method of magnetising the slipper is similar to that employed to magnetise the disc brake described above, but in this case the slipper is drawn down on to the rail, whereby a strong braking action is set up. The writer has not had an opportunity of practically testing this brake on a roadway, but the experiments made at the Tramways Exhibition in London in 1900 were very satisfactory.

Brake Tests.—Tests have been made to ascertain the best methods of stopping cars under various conditions. Cars were run over a marked-off space on a practically level road. The speed was in each case carefully noted, and the brakes were applied at the same point in each case. The results have been tabulated, and from them and from previous experience it appears that for all-round general purposes the hand brake, worked in conjunction with the slipper brake, is the best and most reliable method of regulating the speed of a car. This is especially the case if the rails are greasy, because the wood block thoroughly cleans the rails. For emergencies the electro-magnetic disc brake is the most satisfactory, but it requires to be applied very carefully, as it is very liable to cause skidding. The constant use of electric brakes is not to be recommended, because (1) they are expensive items, and the wear and tear is very excessive; (2) when the gradients are very steep the life

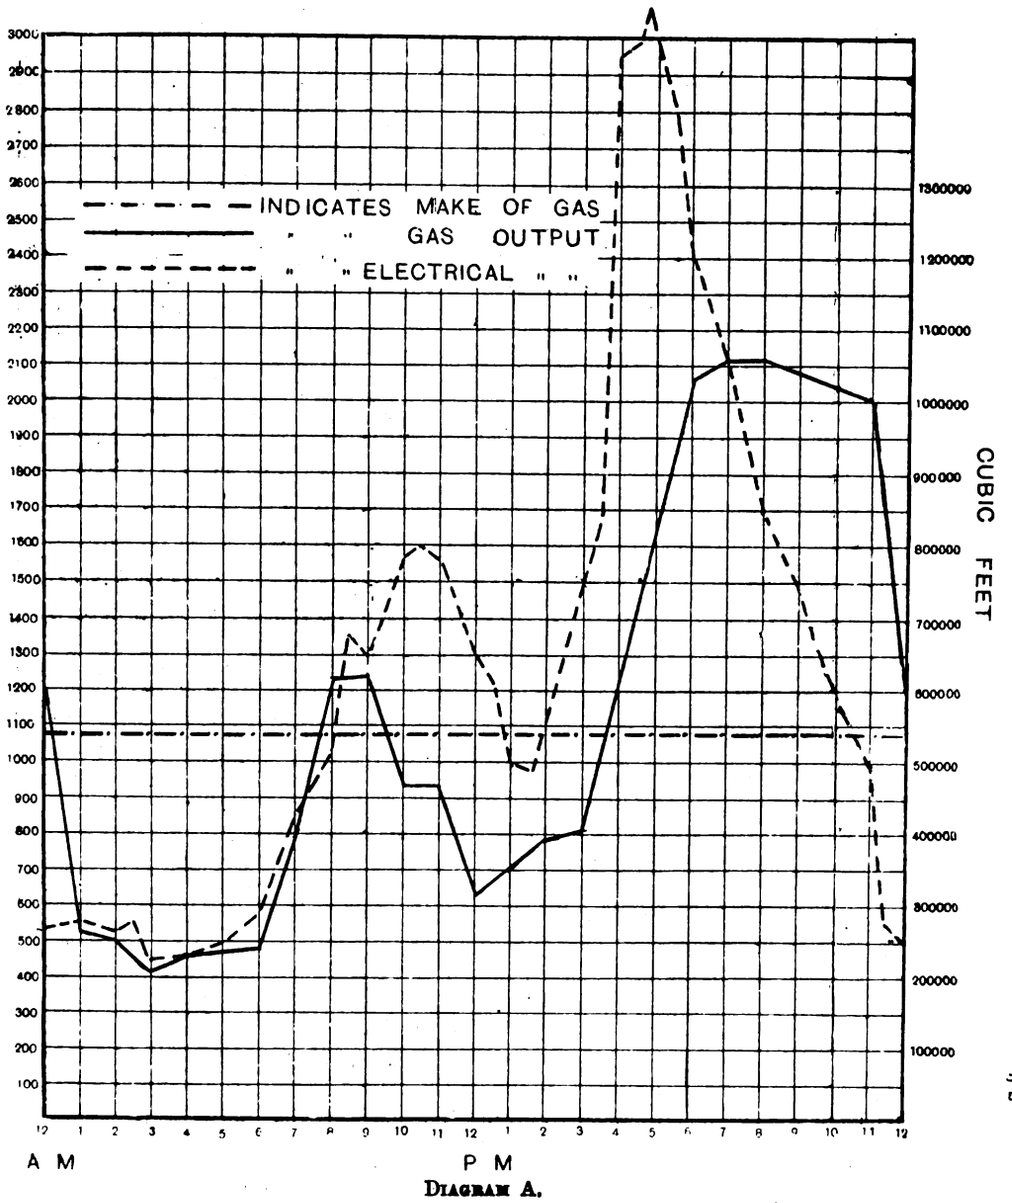

DIAGRAM A.

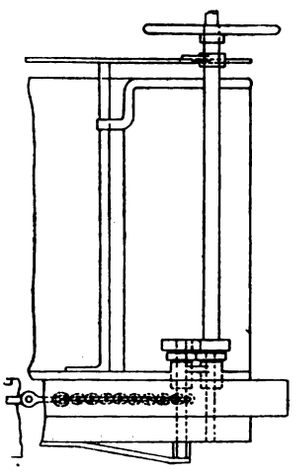

FIG. 1.

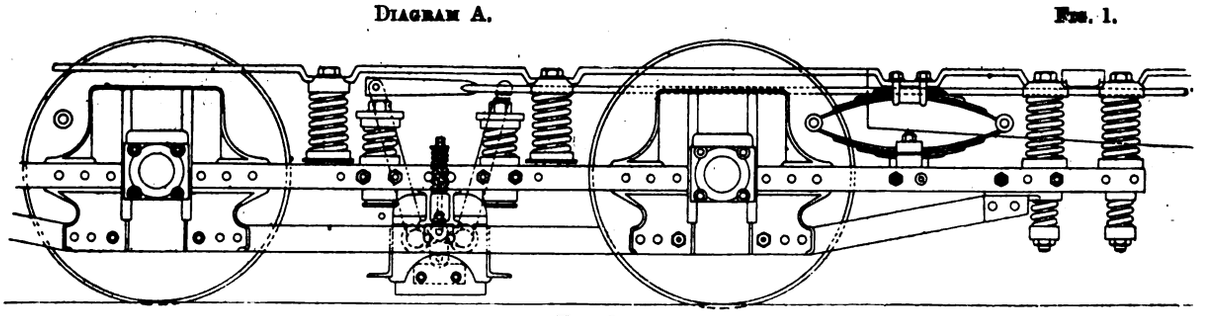

FIG. 1.

Digitized by Google

of the motors will be appreciably shortened, as they will never get an opportunity to cool down.

Mr. COLLINGS BISHOP, of Wigan, complimented the author on his valuable paper, which was of great importance. He believed in the use of a hand brake for ordinary use, a slipper brake for heavy grades, and an electric brake for emergency. This latter should have a rheostatic control to avoid shocks to the passengers and apparatus.

Mr. J. F. C. SNELL, of Sunderland, advocated the members keeping logs of all repairs required, so that in time they might have at their disposal accurate comparative figures of the various costs of upkeep. It would be a good thing if manufacturers would combine an emergency sand-box with the emergency brake to avoid skidding of the wheels. He also advocated rheostatic control.

The meeting terminated by votes of thanks to the two authors for their papers.

The members were then entertained to lunch by the Corporation of Edinburgh. The Lord Provost was in the chair, and after the loyal toasts, proposed "The Municipal Electrical Association," to which Mr. W. A. Chamen replied.

(To be continued.)

Diagram A on the opposite page should have accompanied Mr. Chamen's presidential address given in our last issue. Reference to it will be found on p. 903.

THE VISIT OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO BERLIN.

(Continued from page 853.)

THE DYNAMO WORKS IN CHARLOTTENBURG.

The dynamo works of Messrs. Siemens and Halske Company are situated in Charlottenburg, on the Salzufer. The works were removed to this position in 1886, as the buildings available in the Markgrafenstrasse became too small. The site on the Salzufer, which at the time of purchase was covered with workshops for the construction of machines of another kind, was for a time occupied not only for the construction of dynamos, but also for the manufacture of cables. The further development of business led, in 1899, to the transfer of the cable works to a new site, and the whole buildings available on the Salzufer were occupied with dynamo work. These buildings, as shown in Fig. 1, were built according to the growing and increasing requirements of the manufacture.

The following work is now carried on at the dynamo works: (1) the building of generators, motors, and transformers; (2) the making of cut-outs, fuses, resistances, and lightning arresters, measuring instruments, etc.; (3) the manufacture of arc lamps; (4) the construction of rock-drilling machines. The driving of tools, machines, and lifting appliances is done by electromotors partly separately and partly in groups. The central station is placed near the middle of the works, and contains five steam dynamos furnishing direct currents of 2 by 110 volts. The dynamos are inner-pole machines, the armatures being developed as collectors. The pressure is divided by means of a storage battery; the battery is charged by two motor-generators.

The Building of Generators and Motors.—The building of generators and motors in the main is organised in such a manner, that in one building the erecting and mounting of the machines is carried on, so far as ironwork is concerned; on the other hand, the coils of the armature and the field magnet windings are made in a special building, called the armature hall. This separation of mechanical and electric parts of manufacture prevents an injury of the coil by mechanical influence, or a reduction of insulation by metallic dust. For the convenience of transport, the workshops, as well as the courts, are abundantly provided with tracks and electric travelling cranes. Besides, the machines are placed in the shops in such a way that the transport of pieces upon which work is to be done has been reduced to a minimum. Fig. 2 shows a view of the main workshops, and also gives an idea of the method of dealing with the manufacture. After the castings have been taken out of the foundry they are stored in the court ready for use. Further required work is done by machine tools separately driven by electromotors. Besides the stationary machines, movable tools are used provided with special electromotors, which are of small weight, easily transported by a crane to the worked part, and by means of a flexible cable connected as required. Fig. 3 shows the work upon the stator of a large rotary-current generator on a lathe. Fig. 4 shows a view of the stamping department. Here the sheet metal, of which the active parts of iron are constructed, is cut and stamped. Before being worked by means of a special machine, it is covered with fine paper. The stamping machines work in part with large stampers, which force the whole form with one action out of the sheet. In part the machines stamp the sheets tooth by tooth, as seen in the machines shown in Fig. 4. Single machines, whose models were exhibited in Paris, work entirely independent, taking the sheets from the machine table and giving them at one operation the necessary number of teeth. Then they release the parts, and the action is repeated.

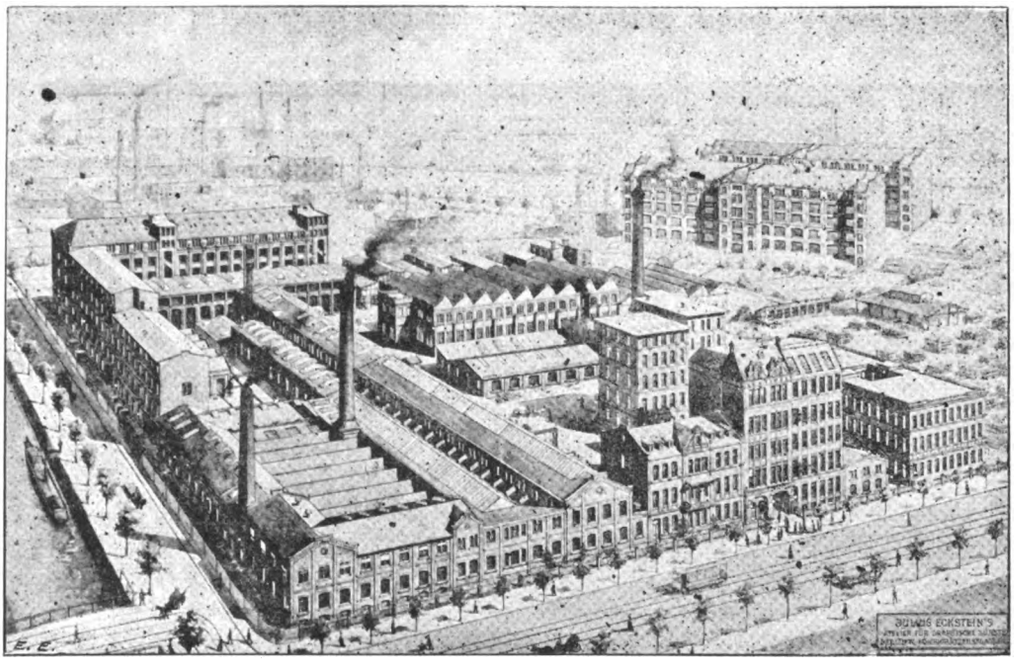

FIG. 1.—Bird's-eye View of the Dynamo Works.

Digitized by Google

The castings and sheets being ready, the machines are fitted in the erecting shops. Fig. 5 shows the fitting of a rotary-current dynamo, the stator having a width of 6m. Next to the mounting-room of machines is the armature hall, devoted to the manufacture of armature and field-magnet winding and commutator building. The armatures, except in some special cases, are constructed on gauges in such a manner that the windings are perfectly

FIG. 2.—Machine Shop.

made, insulated, and so far as intended for the armature, embedded in the active iron. Fig. 6 shows in the foreground the manufacture of field-magnet coils for continuous-current dynamos; while in the background of the hall rotary-current armatures and inductors are wound. Of special interest is the manufacture of inductor coils out of flat copper, bent on special machines. In this part of the building also the connecting of the commutators with the armature is done. The armatures provided with the windings are carefully dried in special vacuum drying boxes in order to produce the best possible insulation. Owing to the expansion of business, special workshops have been constructed for the fitting of small electromotors and street car motors.

When the mounting is completed, a careful test of the machinery is made as to their mechanical and electric relations. Fig. 7 shows a part of the testing-room, in which a rotary-current generator of 13,500 volts is being tested for a pressure of 20,000 volts. The generators of this type, of which at the present time nine machines are under construction, are intended for direct coupling with a 1,000-h.p. turbine of 375 revolutions per minute. After the machines have stood the test they are completed in the motor workshop, and therefrom go the factory stockroom, if not, as it frequently happens with large machines, being at once shipped to their point of destination. For machines which are to be transported a long way, frequently even to countries across the ocean—for example, to the mines of East Asia and South Africa—the carpentry of the works furnishes the necessary and practical packing.

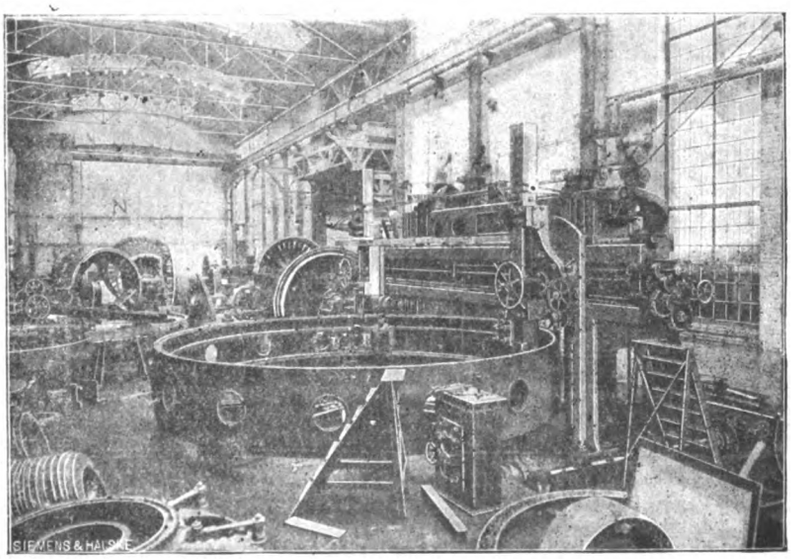

FIG. 3.—Stator of a Rotary-Current Generator on the Lathe.

THE BERLIN ELECTRICITY SUPPLY COMPANY.

The public supply of electrical energy in Berlin was commenced in the year 1885, when a small central station was laid down by the Allgemeine Elektricitäts-Gesellschaft, having as its commencing load some 3,000 incandescent lamps. The new illuminant coming rapidly into favour necessitated an increase in the capacity of the station, and soon the growing demand for electrical energy, not only for lighting but for power purposes, caused other stations to be built, and at the present date the Berlin Electricity Works possess six central stations in addition to numerous sub-stations, having a combined capacity, including the machinery now in construction, of nearly 150,000 h.p., all of which have been built and equipped by the Allgemeine Elektricitäts-Gesellschaft. The curves (Fig. 8) show graphically the increase in the load during the last 10 years, its most interesting feature being the rapid

Digitized by Google

growth of the amount of energy supplied for power purposes and tramways, whereas the increase of energy supplied for public lighting is small, being due probably to the extensive use of the incandescent gas light in the streets of Berlin.

The various stations controlled by the company may be conveniently divided into three groups. The first group consists of the stations lying within the city boundaries, and located as follows: (1) Schiffbaurdamm-Luisenstrasse, 21,000 h.p.; (2) Spandauerstrasse-Rathausstrasse, 14,500 h.p.; (3) Mauerstrasse, 14,500 h.p.; (4) Markgrafenstrasse, 2,100 h.p.

With the exception of the Luisenstrasse station the above are the earlier stations of the company, and generate low-tension continuous-current, which is distributed on the three-wire system. As in other large towns, the heavy cost of ground space made it necessary for the company to build their new stations outside the city. These form the second group, being situated as follows: (1) Oberspree, 54,000 h.p.; (2) Moabit, 36,000 h.p. Both these stations generate high-tension three-phase current, which is brought by triple-cored, lead-covered, and armoured cables buried directly in the ground to various sub-stations in the city forming the third group, and located in the following streets: Mariannenstrasse, 7,500 h.p., and Pallisadenstrasse, 3,650 h.p., fed from Oberspree; Voltastrasse, 5,650 h.p., Konigin Augustastrasse, 5,650 h.p., and Wilhelmshavenerstrasse, 2,700 h.p., fed from Moabit.

The machines in the main and sub-stations in Berlin are arranged to feed two distinct networks—viz., the lighting and power and the tramway network. They are so connected up to the switchboards, however, that in case of necessity they can be interchanged and the stations interconnected, so that in the event of accident occurring at any station its load can be taken up by the others.

As stated above, the lighting of the town is carried out on the three-wire system, the pressure across the outers in the city itself being 220 volts, and in the outlying suburbs 440 volts. The pressure will, however, be gradually changed over to 440 volts throughout. The pressure of the tramway network is 550 volts. The smaller steam dynamos are wound to give a terminal E.M.F. of 110 volts, and are placed as balancing machines between the outers and the middle wire. The larger generators are wound for 220 to 260 volts, and are connected across the outers. In the sub-stations and also in the Luisenstrasse station separate

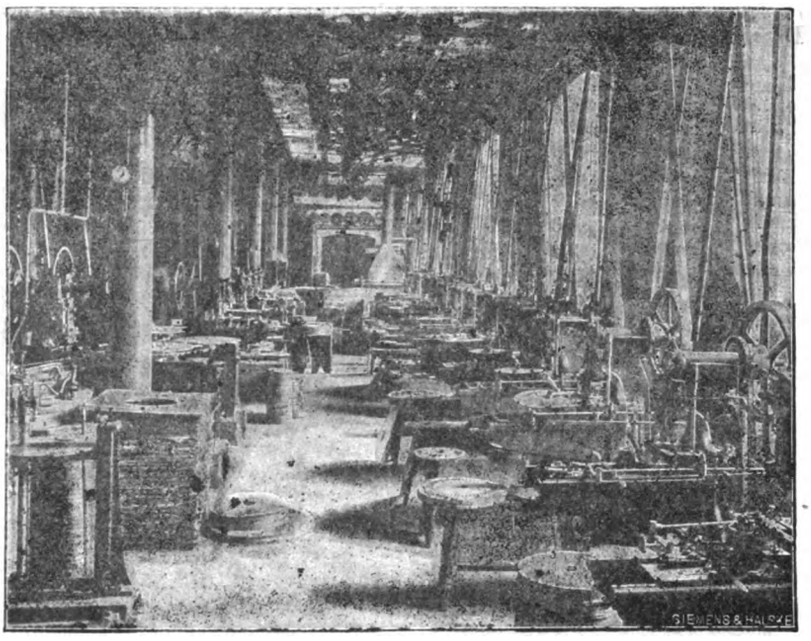

FIG. 4.—Stamping Department.

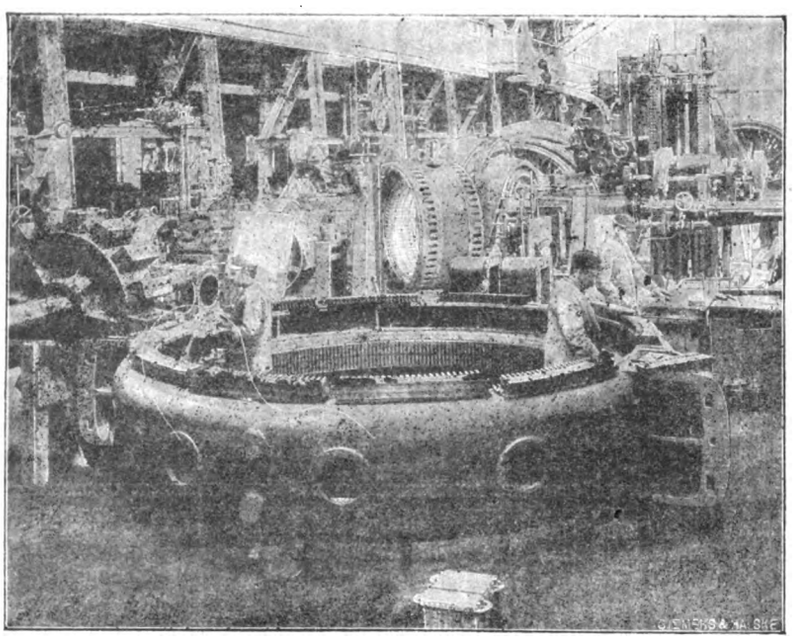

FIG. 5.—Fitting of a Rotary-Current Generator.

Digitized by Google

buffer batteries are provided for the tramway and lighting networks, serving not only to take up the variations in the loads, and thus to reduce the strains on the generators, but also to bear the entire night load.

Preliminary Notice.

[BY OUR OWN CORRESPONDENT.]

By the time these lines appear in print a move should have been made to Dresden, but at present a great effort is being made by the members participating in the meeting to assimilate all the electrical knowledge of Berlin in the very limited time at their disposal. It will be unnecessary to recount the incidents of travel from London; suffice it to say that although the party which left Liverpool-street on Saturday evening last was not large enough to justify a special boat from Harwich, comfortable accommodation was provided by the Great Eastern Railway Company on their steamer, the "Amsterdam." It was coincidence which further provided an exceptionally smooth passage. Arrived at the Hook, the party boarded a special train for Hanover, and commenced their dusty journey through the monotonous country of Holland. In Hanover, which was reached about 4.30 p.m. on Sunday, the real fun commenced, but the first instalment was of an exasperating nature, being a muddle in the hotel arrangements. This prevented some of the members who had the comforts of their ladies to look after from participating in an intended visit to Messrs. Körting's works. However, a comparatively small contingent did eventually get to Körtingsdorf, where it was rewarded for its pains by the inspection, amongst other things, of some very fine gas-engines, including one of 1,000 h.p. in course of erection. Later in the evening the members were the guests of the city of Hanover to a banquet at the Kasten's Hotel, where a very hearty reception was accorded them by the Mayor.

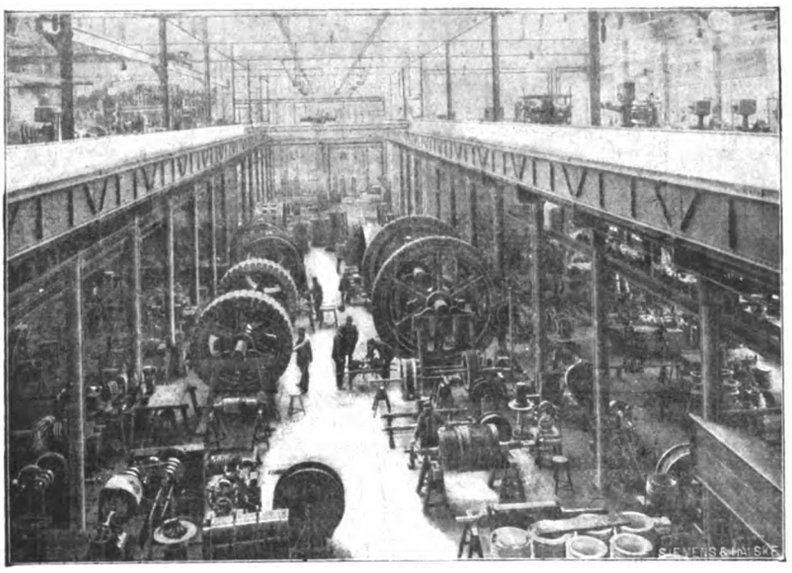

FIG. 6.—Manufacture of Coils and Windings.

The party arrived safely in Berlin on Monday morning, where they were received by Geheimrath Rathenau, the managing director of the Allgemeine Elektricitäts-Gesellschaft, at the company's rooms in the Luisenstrasse. A hundred Nernst lamps were used to illuminate the room in order to demonstrate the advantage of this apparatus. Herr Bussmann, head of the experimental department of the Allgemeine Elektricitäts-Gesellschaft, delivered an interesting lecture on the development of the Nernst lamp, which elicited frequent applause.

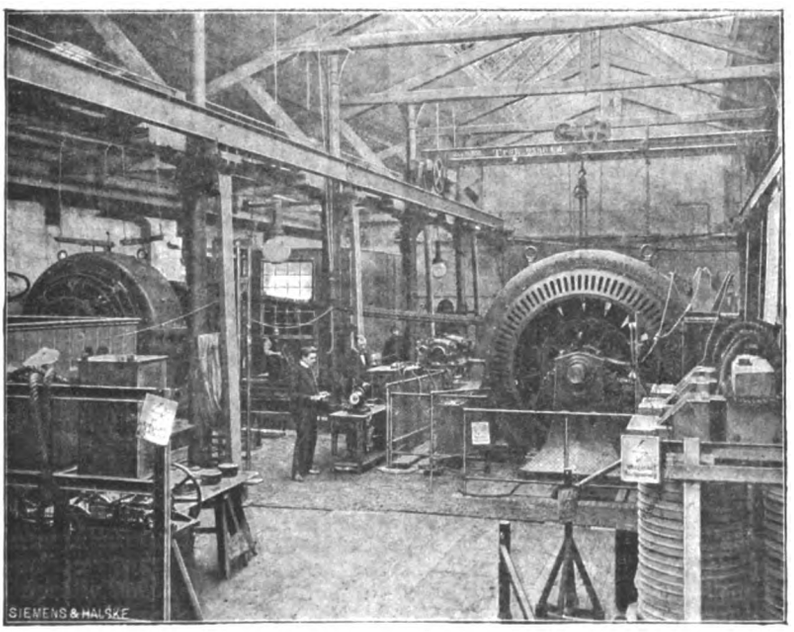

FIG. 7.—Test Room.

The first day was devoted to an inspection of the Allgemeine Elektricitäts-Gesellschaft and the electricity works erected in Berlin by this company. This visit commenced with the central station of the Berliner Elektricitäts-Werke in the Luisenstrasse. A visit to the high-tension station at Moabit, the most modern of the stations

Digitized by Google

belonging to the Berliner Elektricitäts-Werke at which steam dynamos of not less than 4,000 h.p. are at work, and the sub-station in the Königin-Augustastrasse, concluded the day's work.

In the evening a reception took place in the exhibition for fire-prevention and life-saving appliances, where Herr Geheimrath Rathenau welcomed the guests in the name of the Allgemeine Elektricitäts-Gesellschaft and of Messrs. Siemens and Halske. We learn that the proceedings were protracted until the wee hours of the morning, and on

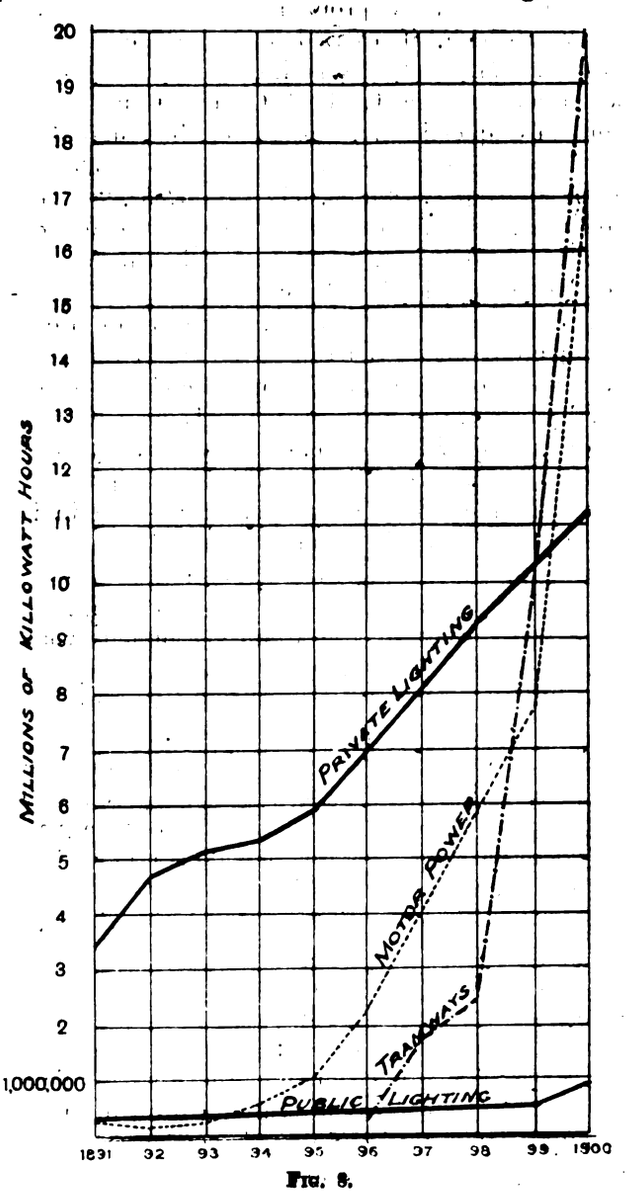

FIG. 8.

Tuesday the works of Messrs. Siemens and Halske were visited.

COMPANIES' MEETINGS AND REPORTS.

GREENWOOD AND BATLEY.

The directors' report for the year ended March 31 shows that after providing for debenture interest and expenses of management, writing off £7,500 for depreciation, and making due provision for doubtful accounts, a profit of £35,627 remains, making with the amount brought forward £36,090. Of this sum the directors have allotted £5,000 towards the cost of completing the installation of electric power throughout the Albion Works, and £1,000 as a provision against contingencies. They have further appropriated £10,000 to the reserve fund, thereby increasing it to £20,000, and they recommend that dividends be declared at the rates of 7 per cent. per annum on the preference shares and of 5 per cent. per annum on the ordinary shares, leaving £4,474 to be carried forward. The buildings, plant, and machinery have been maintained in efficient working order and condition, £5,868 having been expended during the year on maintenance account and charged to revenue. The directors having secured a long lease of premises at Abbey Wood, near to Woolwich Arsenal, with full Government loading license under the Explosives Act, have agreed to terminate the tenancy of the Greenwich loading works and transfer the plant to these more convenient and suitable works. The demand for the De Laval patent steam-turbines, turbine dynamos and pumps, etc., for which this company has the sole right of sale in Great Britain, its colonies and dependencies, also for Egypt, China, and Japan, is steadily increasing.

Presentation.—At the Lincoln Corporation electricity works on Saturday, Mr. Russell, on behalf of the members of the staff, presented a handsome tobacco cabinet to their late chief engineer, Mr. C. S. Vesey Brown, A.M.I.C.E, who is leaving Lincoln to take up the position of general manager to the Northern Counties Electricity Supply Company, Limited. The usual complimentary speeches having been made, the pleasing ceremony concluded with cheers for Mr. and Mrs. Vesey Brown, and the singing of "He's a Jolly Good Fellow." A photograph of the employés has also been taken, and an enlarged copy in frame will be presented to Mr. Vesey Brown in due course.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Now Ready, Vol. XXV., bound in blue cloth, gold lettered price 8s. 6d.

TRAMWAYS IN LONDON.

Persistency in continuing in a wrong course is as discreditable as persistency in doing what is right is creditable. The London County Council is nothing if not persistent. It spends scores of thousands of pounds of the ratepayers' money in trying to rout the water companies. It has formulated tramway schemes which, if carried out, will cost millions of pounds, and is propounding other tramway schemes which, if carried out, will cost more millions. Most of the political papers condemn the action of the London County Council, not upon any question of principle, but upon the ground that such work is largely speculative and may not pay. Some, like the *Globe*, "do not know that, even if it can be shown that it can adopt the *rôle* without loss, its ambition in this respect ought to be gratified." Principle in modern legislation, whether imperial or local, is almost or quite an unknown quantity. Aristotle tells us of a kind of government or monarchy among the Greeks called an Æsymnety, and if that of the London County Council is not Æsymnetic, or an elective tyranny, we cannot otherwise define it. We are no opponents of electric traction in its proper place—and in its proper place there is room for many hundreds of miles within the shores of these islands—but we venture again to assert that in most of the districts wherein the County Council would construct tramways, and thus perpetuate a system of bad roads, the true solution of the problem lies in automobilism and perfect road surfaces. Our roads and streets, compared with those existing in other countries, are generally good, but compared with what perfect street surfaces should be are very bad. The problem for automobilists is rendered far more difficult with the existing road surfaces than it would be with perfect surfaces, and electric traction other than on tramways or railways is at a discount. If the Council is persistent in following a course we deem wrong, we must be as persistent in calling attention to it; and in this new scheme to spend between one and two millions upon further tramways, we think (throwing aside any question of underlying principle) that automobilism will have developed sufficiently far to render it doubtful if the scheme will pay upon business lines. The debt of London is becoming of enormous proportions. Its increasing ratable value is not elastic enough to diminish the rate per pound. Hence the great middle class is being constantly squeezed to provide something for its masters of the *oi poeloi*. The provision of the best form of street surface and the careful sanitation of the streets come within the purview of the local authority, while it has no right to determine or attempt to standardise any particular form of traction.

Heywood.—At a recent meeting of the Technical Instruction Committee Mr. William S. Johnston, clerk of works, electricity department, submitted a report as to the lighting of the technical school by electricity, and the substitution of an electric motor for the gas engine now in use; and it was resolved that Messrs Fryer and Co., Limited, the contractors for the supply of electrical fittings, etc., to the Corporation, be invited to submit a tender for the installation.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

WALTHAMSTOW ISOLATION HOSPITAL.

SIR,—We notice in the issue of your paper dated June 7 an article appearing entitled "The Engineering Equipment of the New Isolation Hospital, Walthamstow." The whole of this article is written as if the British Westinghouse Company, Limited, had obtained and carried out the contract to which the article referred, which is not the case. We were the contractors for the *whole* of the work, and placed an order with the British Westinghouse Company for the gas-engines which they supplied to us. You will see, therefore, that the Westinghouse Company were merely sub contractors to us.

Further, we must call your serious attention to the fact that underneath the block showing a view of the generators the following line appears: "Westinghouse Generators, Isolation Hospital, Walthamstow." This statement is absolutely inaccurate. The generators are "Helios" generators, and were supplied by us as part of our contract.

We notice that the first paragraph of the article states that you obtained the description from the Westinghouse Company, and we are, of course, writing to them in the matter. We are quite sure that you yourself were quite ignorant of the unintentional injustice done to our company.—Yours, etc.,

FRANK SUTER AND CO., LIMITED.
(Harrington Wyman, Director.)

66, Berners-street, W., June 20, 1901.

GILBERT'S SELF-DRIVING WEIGHT OSCILLATING MOTOR.

SIR,—Mr. Arthur E. Gilbert, in his letter in your issue of 21st inst., has greatly moderated his claims for his wonderful motor. In his first letter he wrote, "I can show you something to go back and write upon for the enlightenment of those puzzling their brains over perpetual motion," but in his last asserts he has "nothing to do with perpetual motion," and that his "machine will work as long as a steam-engine." I know of engines which for months at a time are stopped for a few hours only once a week. But to be more accurate, a steam-engine in good order will work as long as it is supplied with energy in a proper manner, and provided Mr. Gilbert does not claim more for his machine, he will not be unreasonable.

It would be more satisfactory to have definite results of a test rather than vague statements, and if Mr. Gilbert will put his machine to drive, say, a dynamo giving an output of 5 kw. or 1 kw., the least that might be expected, in view of his extravagant claims, is that he should communicate the result to your columns.

Mr. Gilbert appears to be very unjust in at least two things. First, he seems indifferent to the fact that your efforts to dissuade him have been sincere, well meant, and based upon a knowledge of the fallacy of his ideas. In the second place, inasmuch as such a machine as he professes to have invented is regarded by the greatest scientists as a practical impossibility, he should not put forward statements he does not prove and reasons for which he does not give.

Perhaps it is well for your space and my time that this matter is to be ventilated in another paper. I hope the ventilation will be thorough.—Yours, etc., G. EVANS.

Aberdare, June 24, 1901.

BIRMINGHAM LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the last meeting of the session, held on the 22nd ult., at the University, Birmingham, Mr. J. C. Vaudrey in the chair, the Hon. Secretary read the following report of the committee:

The committee have to report that on receipt of a memorial signed by 78 local members of all classes, the Council of the Institution of Electrical Engineers granted powers at a meeting on June 25 last year for the formation of a local section of the Institution in Birmingham. At a preliminary meeting on Nov. 19, it was announced that Dr. Oliver Lodge had accepted the position of first chairman to the local section; and Mr. Henry Lea having been appointed vice-chairman, a committee was formed to manage the affairs of the section. At subsequent meetings of the committee the by-laws of the new local section were drawn up, and were approved at a general meeting on March 27. The area included by the local section was defined as consisting of the three counties of Warwick, Staffordshire, and Worcester, notices of meetings, however, being sent on application to any member residing within 50 miles of Birmingham. The committee have pleasure in reporting that the membership of the local section, which had already risen to 110 on Jan. 13, now stands at 123 members, the numbers in the different classes being as follows:

	Jan. 13.	May 22.	Change.
Members	20	21	+1
Associate members	22	34	+12
Associates	50	46	−4
Students	18	22	+4
Totals	110	123	+13

The general meetings of the section have been as follows: Feb. 27, inaugural meeting, address by the chairman, Dr. Oliver Lodge, F.R.S.; March 27, paper by Mr. W. Wyld, associate member, "Polyphase Equipment of Factories"; April 11, adjourned discussion on Mr. Wyld's paper and Mr. A. C. Eborall's paper on "Some Notes on Polyphase Sub-Station Machinery," given in abstract to the members present by Mr. Eborall himself; May 22, annual general meeting of section. These meetings have all been held in the buildings of the university through the kindness of the university council. The Council of the Institution has decided to include Mr. Wyld's paper and the discussion upon it in the *Journal* of the Institution. The committee invite offers of papers from members of the section for the coming session 1901-2, with a view to the formation of a complete programme in time for issue to members before the first meeting in November. They would remind members that the success of the section will be dependent largely upon the original papers received, and the members are therefore asked to realise the need of volunteering to contribute papers, not necessarily sufficiently original or important for inclusion in the *Journal* of the Institution, but with the object of promoting discussions on subjects of interest to members. At the meeting on Feb. 27, the committee at present in office was empowered to act for the next session. Mr. G. S. Ram resigned his place on the committee on March 19 on his transfer to London. The officers for the session 1901-2 are therefore as follows: Chairman: Oliver Lodge, D.Sc., F.R.S. Vice-chairman: Henry Lea, M.I.C.E. Committee: Fred. Brown; Alf. Coleman; Alf. Dickinson; W. E. Sumpner, D.Sc.; Prof. Threlfall; J. C. Vaudrey, M.I.C.E.; W. Wyld. Hon. secretary: D. K. Morris, Ph.D.

Mr. VAUDREY proposed the adoption of the report, and Mr. DICKINSON seconded the motion, which was carried *nem. con.*

Mr. VAUDREY then proposed a vote of thanks to the council of the university for the loan of the room in which all the meetings had been held. Mr. COLEMAN seconded the proposition, and the same was carried unanimously.

Mr. VAUDREY then called upon Mr. Taylor to open the discussion on Mr. Eborall's paper on "Some Notes on Polyphase Sub-Station Machinery."

Mr. Taylor said that, as the paper had already been discussed, he hoped the members would bear with him if he repeated anything that had already been said. He thought the paper was of very great practical value. Mr. Eborall had acted the part of judge, and collected the *pros* and *cons.* of the three classes of sub-station machinery, and had weeded out the first or asynchronous motor-generator, then left the synchronous motor-generator and the rotary converter, and impartially pitted them and then summed up. The members now had to act the part of the jury. He thought Mr. Eborall had not quite done justice to the rotary converter. He had given a short summary of the advantages of the synchronous motor-generator under four headings, and those of the rotary converter under five or more headings, as follows: The synchronous motor-generator—(1) it could be operated from any frequency; (2) simplicity of arrangements for control of pressure on the low-tension side, which was a great advantage, and very simply done; (3) the continuous-current pressure was independent of cyclic variations in the high-tension feeders, and those did not affect the low-tension pressure except when the pulsations were so great as to pull the machine up, which, of course, only happened when anything very serious occurred; (4) with the synchronous motor-generator, owing to any frequency being used, lighting could be done by alternating current, which was a great advantage. The advantages of the rotary converter, Mr. Taylor thought, were: (1) it had 10 per cent. better efficiency at half load than the motor-generator; (2) the overload capacity was 50 per cent. better in the larger

Digitized by Google

machines; (3) the starting current was 40 per cent. less; (4) on removing the whole load on the continuous-current side the rise of pressure was 3 to 5 per cent. less than that of the motor-generator, and thus gave very good regulation; (5) rotary converters were 40 per cent. less in cost for small sizes up to 500 kw.; (6) rotary converters took up less floor space. Mr. Eborall had said the first point against a rotary was that it could not be easily regulated. Mr. Taylor thought that Mr. Eborall had not done justice to the rotary in saying that the simplicity of regulation was not so good as with the motor-generator. As to the third point against the rotary, that the continuous current was independent of cyclic variation in the high-tension feeder, Mr. Eborall gave the disease, and then immediately produced the remedy by saying that choking coils obviated that difficulty, as was shown by what had been done at Prague. As to the fourth point, Mr. Taylor held that both lighting and traction could be done from the rotary converter at any frequency, for he had seen rotaries working at 60 ∼, and the generators were driven by turbines; therefore it was obviously these cyclic variations which affected the running of the rotary at high frequencies, and he thought if we got a perfect engine of high speed—*i.e.*, something like the Parsons steam-turbine—whereby a small number of poles could be used, the cyclic variations would not be nearly so great as with the more commonly used slow-speed engine with a great number of poles, and if we could double the periodicity we would be able then to do both lighting and traction from rotaries as well as from motor-generators. On the Albany-Hudson Railroad, which was 36 miles long, trains were run at 50 miles an hour; there were three three-phase units of 750 kw. each and four sub-stations; and the three motor-carriages had each four motors of 75 h.p. A line like that, which was no toy, was operated with rotaries at this high frequency, and also did lighting as well. The Manhattan Railroad, N.Y., also had large units of rotary converters. These were started by the method of poly-phase-induction motor-generators to give continuous current to the sub-stations. At Glasgow the other thing was done. A small polyphase motor was attached to the end of the shaft of the rotary. Mr. Taylor concluded by saying he hoped he had done justice to the rotary converter, as this was not the case in the paper.

Mr. Dickinson said Mr. Taylor had referred to the high speeds used in this country, and asked what was the speed of the generators on the Albany line, and also what did Mr. Taylor consider high speed?

Mr. Taylor replied, and said he was only speaking comparatively, but that he had in his mind the Willans type of engine. He could not give the exact speed of the Albany generators.

Mr. Jones had nothing to say on the paper, but that probably what Mr. Taylor meant were quick-revolution engines, not quick speed—*i.e.*, not high piston speed engines.

Mr. McLean asked whether two-phase motors would start all right on a load? He had had some correspondence with a manufacturing firm making polyphase plant who had refused to guarantee their two-phase motors to start on a load and they had told him they would not start.

Mr. Wyld had had some little experience with the equipment of sub stations, although not polyphase. Some time since he had charge of the erection of several fairly large sub-stations equipped with synchronous motor-generators for converting single-phase high-tension alternating current to continuous current, and remembered the difficulty he had in getting them run up for the initial charge of the battery, for, of course, the high-tension current could not be put on to the motor until it was up to synchronous speed, and there was no continuous current available to run the low-tension side as a motor. In one case arrangements were made with a prospective consumer for power to drive a temporary dynamo from which current was taken through the mains to the sub-station, and the motor generator run up to speed and paralleled on to the high tension feeder. Mr. Wyld, therefore, agreed with Mr. Eborall in advocating the installing of a small asynchronous motor in the sub-station for running up the larger machines, as that was quite practical in a polyphase station, but, unfortunately, the usual motor-generators or converters were too large for single-phase motors to start up. With regard to the hunting of the motors, Mr. Wyld appreciated all Mr. Eborall had said in his paper on the matter, for he knew how the two or three motor-generators used to behave when they were all running in parallel, with perhaps two or three alternators at the generating station. When a "short" occurred on the mains, or a bad parallel at the generating station or any of the sub-stations, one of them would commence hunting, and that affected the others, and then possibly one or two of them would fall out of step—and, of course, blew their fuses—and these, going at 2 000 or 3,000 volts pressure, were not conducive to good regulation. These machines were worked at a periodicity of 75, and were single-phase, so that it was not to be expected that they would run so well as polyphase machines at a much lower periodicity. In reply to Mr. McLean's question *re* the two-phase motors starting on load, Mr. Wyld did not think he need fear much in that direction, for he (Mr. Wyld) had not as yet known any of his three phase motors to jib, and he did not see why the two-phase motors should.

Mr. Taylor said there was one thing he would like to mention, and that was that Mr. Eborall evidently did not think that continuous currents had to be varied, for his paper was entirely on the question of converting polyphase into continuous current, and a good deal had been heard just recently against continuous current. Perhaps some other speaker might have some further remarks to make on this point.

Mr. Wyld thought if Mr. Taylor referred to the last paragraph in Mr. Eborall's paper he would find that Mr. Eborall was by no means advocating continuous current, and, in fact, stated that although continuous-current sub-stations were necessary and advisable in certain cases, he was of the opinion that the best solution would be to distribute the polyphase current from ordinary transformer sub stations; and by that means the best results both from a technical and commercial point of view, would be obtained.

Mr. F. Brown asked what was the lowest periodicity that could be used for lighting work?

Mr. Taylor replied that he thought 30 ∼ was the minimum for incandescent lamps.

Mr. Vaudrey said he hardly felt in a position to sum up the debate, for, he said, he knew so little about polyphase work. One feature of the polyphase current was the engine power required. Only recently engineers had appreciated the high-speed engine, and he noticed that the high-speed engine was now being adapted to polyphase generators. He had recently had the opportunity of seeing a 1 200 h.p. Willans engine and Brown-Boveri three-phase alternator tested at the works of Messrs. Willans and Robinson. The power was absorbed in tanks 8ft. square by 6ft. deep, and the three leads were taken to the tanks and about 6in. or 8in. exposed in the water. The whole tank seemed on fire, and he thought this rather a novel way of absorbing 1,200 h.p. at 6,000 volts. Mr. Taylor had given 30 periodicity as a minimum for lighting purposes. Derby had 30, and it was an utter failure so far as arc lighting went, and was very little better for incandescent lighting. Fifty periodicity was about the lowest practically.

Mr. Taylor said that there was a difference whether 100 or 200 volt lamps were used, the effect of a low periodicity being marked on the 100 volt lamps.

Mr. Vaudrey, continuing, said Mr. Eborall had said that, to be a success, the generator ought to be fitted between the cranks of the engine. On the Willans it was at the side of the engine on the end of the shaft, and worked admirably. Mr. Eborall no doubt was thinking of the American slow-speed type of engine.

Mr. Vaudrey then explained an idea which had been suggested by Dr. Sumpner, that if at the meetings a paper was not forthcoming, some person should raise a subject for discussion. The first thing that had occurred to him was the question of "Boilers for Central Stations." Continuing, Mr. Vaudrey said the question of boilers was the very important one of steam generating plant, and his experience was that an electrical engineer without a really practical knowledge of engineering generally was only half an engineer. In a large generating station the generation of steam was most important. There were so many kinds of boilers now on the market that it was important to know which was good and which bad practice. The determining factor was that of the space available, then the value of land, and, perhaps, the actual cost of putting down the boiler had a great deal to do with it. The value of land had naturally brought the water-tube boiler into great use. No doubt if stations had been put outside great cities such as London, as was now being done, the Babcock and Wilcox boiler would not have been nearly so common. Then there were the Lancashire, dry-back, Babcock and Wilcox, Root (probably the Babcock and Wilcox was the outcome of the Root), Stirling, and Niclausse boilers. The Lancashire boilers which were long cylindrical boilers up to 30ft. long, with flues from end to end, with Galloway tubes across them, were now made for a working pressure up to 180lb. per square inch. The dry-back boiler, also cylindrical, had the advantage of being much shorter than the Lancashire, being only 11ft. long. Tubes were let through the boiler from front to back. The water-tube boilers were the Babcock and Wilcox, Root, Stirling, and Niclausse; the difference between these and the other class of boiler being that the water in these circulated through the tubes, whereas in the other class the water was outside the tubes. The question was which boiler to select. It was impossible to get a Lancashire boiler in such places as cellars and very confined places, therefore the water-tube class had to be used. There were, however, a great many Lancashire boilers in use; and why were there so many? The Lancashire boiler was so good for inspection and cleaning, and had a large storage for steam. Although its steam-raising power was not so rapid, it had some very good qualities. The dry-back boiler had much in common with the Lancashire, but the effects of expansion and contraction were not so serious, as the boiler was much shorter. It was a quick steam raiser, but the objection to it was the number of small tubes. The Babcock and Wilcox boilers were very quick steam raisers, and were very useful and convenient for confined places such as were to be found in towns, also for sending out to the Colonies, as they could be put together in their places, and they worked very well. The cost of cleaning, however, was very great, and unless the water used was very clear, the tubes gave trouble. More evils arose from bad water than from anything else. The Birmingham water was supposed to be good, but he had found it not so, and if he was putting down a new station he would put down a water-purifying plant. In one year the Birmingham water would deposit nearly an inch of incrustation, so the cost of purifying would soon pay for itself. The danger of incrustation was that the plates of the flues got burned. Further, the question of water was important in respect to the fittings and cocks, and on no account whatever should those so-called compounds for softening the water be used, as these often brought more trouble than the hardness of the water. Boiler fittings ought to be most carefully selected. He had once had some fittings supplied by a new firm making fittings, and these were to all appearances like those of a very well-known maker, but when they came to be used they did not last six months. Every maker did not seem to know the right mixture of metal, and, therefore, only fittings of the very best makers ought to be used.

Digitized by Google

Mr. Jones thought the meeting ought to be grateful to the chairman for his remarks, and that all would agree with him in his remarks re the class of boiler to be used. Not only space, but safety was an important item in deciding upon what class of boiler to use, and he thought the water-tube much safer than the Lancashire. In the Babcock and Wilcox, as he understood it, owing to the rapid motion through the tubes all the deposit of scale was carried away. The Lancashire boiler plates were weakened by heating when the boilers became encrusted, but in the water-tube boiler that was not the case, so that even for bad water the water-tube was the one to adopt. In locomotive boilers he had found oak tan bark liquid answer very well indeed.

Mr. F. Brown said that circulation was supposed to take place in the tubes of the water-tube boiler, but he knew a place not very far from the room they were in where the tubes had got furred up entirely in a week. Birmingham Canal water was used.

Mr. McLean only put washing soda into his boilers, using Thames water, and it answered very well. Locomotive boilers he had found the worst to clean at the corners of the fire-boxes. In the old Grosvenor Gallery station, where the boilers were pressed very much, there was trouble with the London water, for the tubes got so badly furred that a lead pencil could not have been passed down the tube. There were four boilers, and they had each to be cleaned out once a month. With Lancashire boilers one could get inside and see what really was going on, and could make a very careful examination; in a locomotive boiler that could not be done. The fittings were very important, especially the blow-off cocks.

Mr. Vaudrey, in replying, said, with regard to Mr. Jones's remarks about blowing-off the boilers, he thought that a very crude method, and no doubt it would become a nuisance if done often in a large city such as Birmingham. At Liverpool he had seen scale ¼in. off a rivet head, and that was, of course, with lake water, but it turned out afterwards that there had been so much grumbling about the very soft water that part of the old supply from some part of Lancashire had been turned in with the new supply. He did not consider the Babcock and Wilcox boiler suitable for bad water, as it deposited even worse than the Lancashire boiler.

CATALOGUES RECEIVED.

Messrs. D. Bruce Peebles and Co. have forwarded to us their new catalogue, which has recently been issued, and which for general finish and arrangement will compare favourably with any other maker's list that we have had before us. It will be remembered that this firm manufacture "P. P. P." dynamos and motors, so called because the three gentlemen who practically are responsible for the work all have their surnames commencing with P. The firm, although it only commenced manufacturing dynamos and motors some few years ago, has already supplied some 50,000 e.h.p. of generating machinery, and its electric motors have found very large use in central-station work and in power distribution. In the catalogue there are reproduced a number of most interesting illustrations of the shops in which these electric motors and generators are made, and the specifications given afterwards of the motors themselves show the liberal margin which the firm allow in their goods. Farther on in the list, specifications are given of the dynamos, ranging in size up to 500 kw., and here again the details are such as will commend themselves to consulting engineers. The prices given in the list are also supplemented by the over-all dimensions of the various machines, so that the catalogue will be of great value to engineers when drawing up designs for new works.

Messrs. Richardsons, Westgarth, and Co., Limited, of Hartlepool, send us their list of "B. B." continuous-current machinery. We notice that the firm are making their dynamos and motors in a number of sizes ranging in voltage from 65 to 500 volts. From the specifications of the various machines given in this list, the dynamos and motors would appear to be manufactured on the best lines and with the finest materials.

A new pamphlet on the lubrication and formation of bearing surfaces, and also a revised price-list of the firm's pressure gauges, have just been issued by Messrs. Dewrance and Co., of Great Dover-street, London.

FORTHCOMING EVENTS.

FRIDAY, JUNE 28.

Physical Society.—At 5 p.m., ordinary meeting in the Wheatstone Laboratory, King's College. Papers: "The Effect of a High-Frequency Oscillatory Field on Electrical Resistance," by Mr. S. A. F. White; "The Spectrum of Cyanogen," by Mr. E. C. C. Baly and Dr. H. W. Syers.

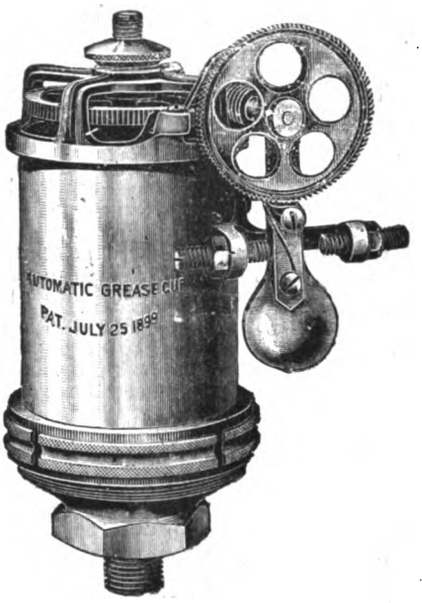
Society of Arts.—At 9 p.m., annual conversazione at the Royal Botanical Gardens.

THURSDAY, JULY 4.

Rontgen Society.—At 8.30 p.m., annual general meeting. Mr. G. Bowron will show an Oscillometer for Measuring the Current and Oscillations in the Secondary Circuit of an Induction Coil or similar apparatus.

"TIC-A-TOC" LUBRICATOR.

Messrs. Stern Bros., of 57, Gracechurch-street, E.C., have recently placed on the market a new automatic lubricator, which goes by the name of "Tic-a-Toc." It will be seen from the accompanying illustration that the design of this automatic grease-cup is exceptionally neat, and, what is of more importance, the mechanical construction is extremely simple. In action, too, simplicity is also a prominent feature. The throw of the crank-pin or eccentric of an engine operates the pendulum of the lubricator. This forces the plunger—fast or slow as required—through the grease-cup. It is claimed that the ordinary engine, running 10 hours a day at a speed of 150 revolutions a minute, will take 11¾ days to empty the pint cup. The



quantity of the lubricant, however, is easily regulated by increasing or diminishing the swing of the pendulum, and if desired, the lubricator can also be operated as a hand-compression cup while the engine is running. The stem of the plunger extending through the top of the cup indicates the amount of grease remaining in the cup. Messrs. Stern Bros. are making these lubricators in sizes ranging from 2in. to 3in. outside diameter. In the first size the extreme height of the lubricator when filled is only 7½in., while the largest size brings this figure up to 11¾in. The capacity of these two sizes is 4oz. and 18oz. of grease respectively. For use on eccentrics of engines which run continuously, or for a longer time than the cup will feed with one filling, special attachment is provided. We understand that the device has been patented in England, the United States, and other countries.

APPOINTMENTS VACANT.

Engineer in Charge of Station, Stepney Borough Council, must have had previous charge of plant consisting of water-tube boilers, high-speed engines, direct-current dynamos, etc., July 8. Details in our advertisement columns.

Shift Engineer, Huddersfield Corporation tramways, £100 per annum, July 1. Details in our advertisement columns.

Electrical Engineers, Dewsbury, £250 per annum, to be increased at the end of 12 months to £300, July 4; tramways, Council of the city of Wellington, New Zealand, July 20. Details in our advertisement columns.

Meter and General Testing Superintendent, Stepney Borough Council, July 8. Details in our advertisement columns.

Meter-Room Assistant, Stepney Borough Council, July 8. Details in our advertisement columns.

Canvasser, Ilford district, £2 per week. Applications must be delivered to Mr. W. J. Woodward, electrical engineer, 7, Cranbrook-road, Ilford, by July 3. Details in our advertisement columns.

Qualified Gentleman to take the position of head of the physics and electrical engineering department, £500 per annum, June 29. Details in our advertisement columns.

Clerk, Ealing District Council Electric Lighting Committee. Details in our advertisement columns.

Resident Electrical Engineer, borough of Swansea electricity works, July 11. Details in our advertisement columns.

Electrical Fitter, Grove Fever Hospital, Tooting-grove, Tooting Graveney, S.W., 30s. per week, July 4. Details in our advertisement columns.

Switchboard Attendant, Devonport Corporation electricity works. Details in our advertisement columns.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any question should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

389. A corporation with a continuous-current electricity supply are contemplating the hiring out of motors, and require a scheme to be fully worked out and submitted to them for approval. What are the essential points to be observed in the drawing up of this scheme, more particularly with regard to the borrowing and repayment of loan?—G.

390. A Thomson-Houston series circuit is burning with full load of 50 arc lamps, when earth faults suddenly develop, one on the positive main at the third lamp (counting from positive of dynamo), the other on negative main close to dynamo (after No. 50 lamp). The faults are very pronounced, but lamps Nos. 37 and 42 continue to burn, all the others, with exception of Nos. 1, 2, and 3, being out. Why should lamps Nos. 37 and 42 continue to burn?—F. C. J.

ANSWERS.

Question No. 383.—I have charge of an installation comprising gas-engine and shunt dynamo of about 8 kw., voltage 100. There is also a battery of 53 cells. I wish to charge up 20 new cells. What is the best means of obtaining a steady current at reduced voltage?

[The replies to Question No. 383 are neither so good nor so comprehensive as usual, and several are complementary of the other; so we give a large number of the answers, equalising the prizes.—ED *E. E.*]

Answer to No. 383 (*awarded* 5*s.*).—There must surely be a mistake in this question; the charging voltage for 53 cells should be 135 to 140 volts, not 100 as stated. In order to charge up 20 new cells, the E.M.F. required will vary between 40 and 55 volts. Now this will mean that the dynamo must work at one-third the usual voltage. This reduced E.M.F. could be obtained by either running at a lower speed, or by inserting a large external resistance in the shunt circuit. In either case the result is the same: the field flux is considerably diminished, and as the current output will be the same for the 20 cells as for the former 53, in all probability it will be impossible under such conditions to get sparkless commutation; and it may be that the armature reactions will be stronger than the forward induction, when most disastrous sparking will result.

Two simple methods are, however, open for adoption. The first is to run the dynamo at the usual speed and voltage, and put an additional glass box in series with the 20 cells to be charged; if this is filled with *slightly* acidulated water, and the charging current is passed through it from two lead plates, it will form a resistance in the main circuit which is variable at will, and which can be utilised to absorb the excess of voltage between that required for the 20 cells and that given off by the dynamo.

The second method is this: The writer assumes that the 20 new cells are required to replace that number which have worn out; this leaves 33 in good condition. If, now, the shunt coils, which were formerly probably in series, are connected to these 33 cells in parallel, but still through the regulating switch and resistance, the dynamo will now be a separately excited, in place of a shunt, machine, and the forward induction will be practically what it was before. It will now be an easy matter to get the 40 to 55 volts required, all that is necessary being to see that the armature is revolved at the requisite speed for this purpose. In this case it will be necessary to watch the charging very carefully, as a separately excited dynamo is not so suitable as a shunt machine for the purpose of charging cells.—M.

Answer to No. 383 (*awarded* 5*s.*).—The best method of charging up new cells is by means of a small booster, but since such is not included in the installation, the best method would be to charge these cells from the dynamo. This will best be accomplished by inserting in circuit with the cells some form of resistance to reduce the pressure of the dynamo to that required by the cells when fully charged. If we allow a pressure of 2·5 volts per cell when fully charged, then voltage required by battery = 2·5 × 20 = 50 volts, ∴ drop of pressure in resistance will be (pressure developed by dynamo) − (pressure required for cells)—*i.e.*, 100 − 50 = 50 volts.

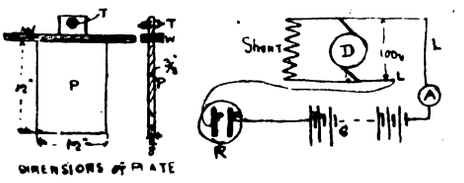

FIG. 1.

A cheap and effective resistance can be made by inserting in a small tub or tank, R (Fig. 1), two plates, P P, either of lead, iron, or carbon, these plates being held in position by means of two strips of wood, W W, placed across the mouth of the tub. To each plate is fastened a terminal, T. The tub is filled with sulphuric acid (5 per cent. solution). Fig. 1 represents the connections, L L are the leads from the dynamo, A an ammeter, C the cells to be charged, and R the liquid resistance. The great advantage of a liquid resistance is the perfectly gradual manner in which the current can be regulated. As the cells gradually become charged it will be noticed that the current gradually decreases. The current can be increased (*a*) by taking resistance out of the shunt, (*b*) by decreasing the distance between the plates, or the current can be decreased by increasing the distance between the plates.—L. B. H.

Answer to No. 383 (*awarded* 5*s.*).—The writer concludes that "A. P.," when he charges the cells, increases the speed of his dynamo to get the 53 × 1·6 volts = 138 volts. The 20 cells may be charged by doing the reverse—*i.e.*, decreasing the speed of the dynamo by putting a larger pulley on the dynamo or a smaller one on the engine, the speed of the engine could be altered, but it would not be found satisfactory. If the pulley on the dynamo was changed, the new one would have to be $\frac{138}{52} = 2{\cdot}6$, times larger (52 = 20 × 2·6). The expense would no doubt prohibit the use of a motor-generator or a "negative" booster (if the term may be used). The motor-generator would consist of a 100-volt motor, driven by the dynamo or accumulators (53 battery) coupled to a 52-volt dynamo. The "negative" booster would consist of the usual machines, motor and dynamo, the latter in series with the main generator, but in this case the dynamo side of the booster would be in opposition to the main voltage, so that the voltage of this dynamo would be 100 − 52 = 48 − less the C R loss in the armature.

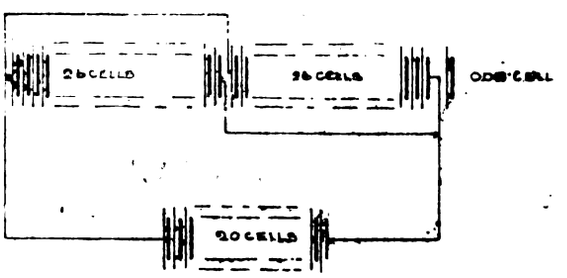

FIG. 1.

Yet another way, and by far the best from costs point of view, is to charge the 20-cell battery from the 53-cell battery. This may be done by cutting out the odd cell, cutting the remainder in two, and putting them in parallel

Digitized by Google

(see Fig. 1). This would give a voltage of $\frac{52 \times 2}{2} = 52$, voltage necessary for charging 52; so this would be the best way, as the alteration only needs a few yards of wire and needing very little attendance. A more efficient way, however, is to put the 53 cell battery in parallel as above, and connect the 20-cell battery in series, charge with the dynamo (Fig. 2). You would have to run the dynamo a

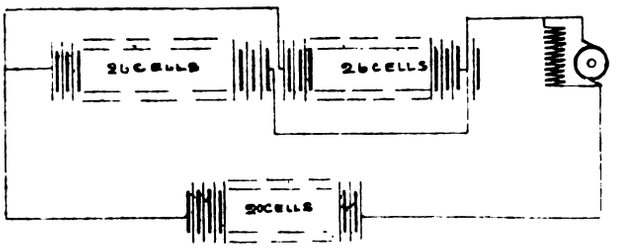

Fig. 2.

little slower $(20 \times 2{\cdot}6) + (2{\cdot}6 \times 2{\cdot}6) = 52 + 67 = 119$ volts needed. The difference in speed being so small, could be taken up by the gas-engine.—T. W. S. H.

Answer to No. 383 (*awarded* 5*s.*).—The most economical way to do this, if time and circumstances will permit, is to put one or more of the new cells in series with the 53. In most cases a good margin of adjustable resistance is provided in the shunt coils of the dynamo, so that its E.M.F. can be raised or lowered very considerably. It must also be borne in mind that a small charging current is much more beneficial to new cells than a large one. In many cases five new cells could be put in the charging circuit in this way quite easily, especially in summer, and they could be disconnected before starting the discharge. A few days of this treatment would charge all the 20 new cells a good deal better than hurrying them with the largest current they could take, for this is very apt to strain and disintegrate the plates. And again, this plan is economical, because it expends no more energy than is actually required for the work to be done. No work is done on useless resistance, and the little extra time employed in charging at a somewhat reduced current is well invested, and will show itself as an improvement in the condition of the battery and the light. If all the 20 new cells must be charged at once and as quickly as possible, and there is no adjustable resistance in the shunt coils of the dynamo, then it would be well to take this opportunity to add it. Its resistance should be sufficient to reduce the E.M.F. of the dynamo to about 50 volts, the amount required to charge 20 cells under normal conditions. If this cannot be done, then a suitable resistance coil must be added in the charging circuit to reduce the E.M.F. of this circuit at the terminals of the 20 cells to about 50 volts. It will be easy to calculate the resistance required, because the volts to be lost will be obtained by multiplying the current in amperes by the resistance in ohms—*e.g.*, suppose we have a current of 20 amperes, and wish to lose 50 volts, then $\frac{50}{20} = 2\frac{1}{2}$ ohms, or $2\frac{1}{2}$ ohms $\times$ 28 amperes = 50 volts. The question does not state the number of amperes used. Galvanised iron wire makes a good, cheap resistance coil, and it will safely carry 1,500 amperes per square inch of sectional area.—F. G. A.

Answer to No. 383 (*awarded* 5*s.*).—A simple way to charge up your new cells would be to connect up a water resistance in series with your cells. A water resistance may be made in the following way: Procure a fairly wide water-barrel with one end open and four pieces of wood about $2\frac{1}{2}$in. square and long enough to project a little way over the barrel at its greatest diameter. If two pieces of sheet lead about $\frac{1}{8}$in. thick are now got, all the material necessary for the water resistance is at hand. First connect up the sheet lead and wood as shown in section in Fig. 2; Fig. 4 being a side elevation. Splay the ends of the cables connected to the sheet lead as shown in Fig. 3. Slip the cables in adjacent to the sheet lead and screw up by bolts to ensure good contact. Put the countersunk nut on the inside, and do not put two nuts in the two top connections opposite each other—*i.e.*, stagger all countersunk nuts—so as to avoid any chance of short-circuiting.

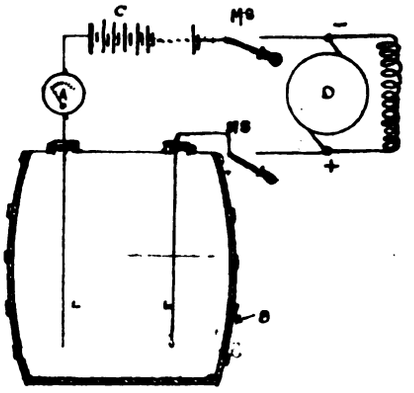

Fig. 1.—C, cells; M S, main switches; A ammeter; D, dynamo; L, lead plates.

The full connections for charging are shown in Fig. 1. Having filled the barrel with water, put the lead plates in the barrel as far apart as possible. Run up the dynamo to its normal voltage—100 volts. Put in all the switches necessary for charging. Advance the plates, L L, towards each other a little bit, but do not get them too near unless

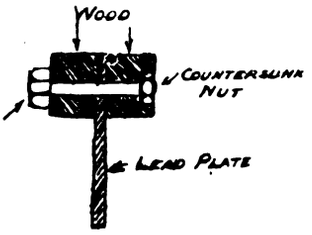

Fig. 2.

Fig. 3.

absolutely necessary. Keep them about a foot apart, and if the current is not by this time at the proper point, add a little sulphuric acid drop by drop, stirring well each time until the current gets to the proper plate, shown on ammeter, A (Fig. 1). It is not advisable to give new

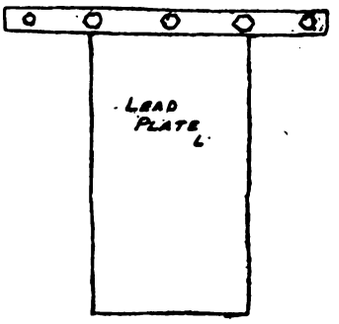

Fig. 4.

cells too much charging current or charge them too rapidly on a first charge, and about half the usual current given to the cells would be quite sufficient.—S. L.

Answer to No. 383 (*awarded* 5*s.*).—In order to pass the correct charging current through 20 new cells, the charging voltage will have to vary from a very low value, say 10 volts, at the commencement to about $2\frac{1}{2} \times 20 = 50$ volts at the end of the charge. These low voltages can be obtained without trouble from the 100-volt dynamo by reducing the exciting current sufficiently. In order to prevent the field becoming unstable at these low excitations, it will, however, be necessary to separately excite the magnet from some independent source—in this case from the whole or a part of the 53-cell battery. That this method of volt reduction is perfectly satisfactory in practice is evidenced by the wide use of the ordinary charging booster in battery stations. These boosters are, in the majority of cases, quite ordinary dynamos, separately

Digitized by Google

excited, and giving volt variations quite as large as the above by variations in the exciting current alone without any sparking or other trouble. In our case the dynamo would be excited off about 20 or 30 of the 53 cells, and a large regulating resistance would be inserted in the field circuit at the commencement of the charge and gradually cut out as it proceeded. Or, in order to avoid the use of a specially large resistance, the number of cells used for exciting could be gradually increased as the charge proceeded, and in this way the shunt resistance, which is, no doubt, already in use with the dynamo, would be quite sufficient.

As an alternative method the 20 new cells could, of course, be connected direct to a certain number of the 53 cells, and this number could be gradually increased by means of the ordinary battery switch so as to maintain the charging current constant at its full value throughout. This method has, however, the disadvantage of leaving a certain number of the 53 cells partially discharged, and unless these are separately recharged they are liable to give trouble when the battery as a whole is next discharged.—Q.

Answer to No. 383 (*awarded* 5*s.*).—The question leads one to suppose that the 53 cells are either not charged in series, or, if they are, they are not the usual two-volt ones, or that the shunt dynamo in opposition to one's motions is capable of being pressed up to somewhere like 120 volts when charging the cells in series. As the dynamo has evidently been accustomed to charge these cells, we will leave speculating and pass on to the consideration of the best method of obtaining a steady current at reduced voltage to charge the 20 new cells, which, I take it, have to be charged separately from the 53.

There are two ways of altering the voltage of the dynamo: by reducing the speed of rotation; by weakening the field through placing a resistance in series with the coils of the field magnets. Further, the voltage between two points of the external circuit may be reduced by placing a suitable resistance in the remaining part of the circuit, while the voltage of the dynamo remains constant. Reducing the speed of dynamo we may at once dismiss, being unstable and uncertain in its effect. The introduction of a resistance into the external circuit, although very wasteful and uneconomical, requires the least disturbance of existing connections, and has simplicity to recommend it. I would suggest that "A. R." connect his 20 new cells in series, and put a voltmeter across the terminals to find their united E.M.F.—say it is 40 volts. Taking it as such, about 50 volts will be needed to charge the cells—that is to say, 40 volts will be absorbed in overcoming the back E.M.F. of the cells and 10 volts in forcing current through the cells. If the voltmeter were across the cells' terminals while charging was in progress, it would, when the above conditions held, show 10 volts. Now connect up dynamo and cells with the voltmeter across end cells, and leave a gap in the circuit. Close this gap with an adjustable resistance. Probably five ohms would do, but more at the start would be better. A water resistance is good if there are no other adjustable resistances handy. Make it by fastening to each end of the wire at gap a lead plate one square foot or more in area. Suspend the two plates in an oblong glass or lead-lined wooden box, taking precautions that there are no contacts anywhere. Fill with water until plates are fairly well immersed, then make the water conduct by adding a little acid by degrees. By shifting the plates nearer together the resistance may be adjusted further, only take care not to touch the plates. Adjust till 10 volts are shown on the voltmeter across cells, and you will be all right unless the water overheats, which requires watching while the charging progresses.

Now let us consider the effect of putting resistance in series with the field of dynamo, to weaken the field and so reduce the volts—a method which appears far more economical and better, although perhaps causing a little more trouble. As before, 50 volts are needed for charging the cells, and in this case the 50 volts are needed at the dynamo terminals. Disconnect one of the wires of the field magnets and close the gap so formed by means of an adjustable resistance of, say, rather greater value than the resistance of the shunt field; the resistance has not to carry any great current, and so need not be of very special make. Use a water resistance if it is convenient, but any adjustable resistance would answer. Now, while the dynamo is running at normal speed, adjust this resistance until the required 50 volts across the terminals are obtained on the dynamo. Then switch in the 20 cells, taking the ordinary precautions as to current being in right direction, and readjust the resistance, if necessary, until the required amount of 10 volts are shown on voltmeter. Things may then go on till the charging is finished. It is probable that the 100-volt meter will not give very correct readings at 10 volts, a matter which must be taken into consideration.

One other matter worth mentioning is the advisability of having an automatic cut-out acting when the current drops to a certain amount; it is easily arranged for, and prevents accidents and annoyance.—W. T. S. B.

Answer to No. 383 (*awarded* 5*s.*).—The fact that a gas-engine is employed in the case mentioned, introduces difficulties which would not be present if the plant was steam driven.

Now, the volts generated by any dynamo depend upon three factors: (1) the armature speed; (2) the field strength; (3) the number of turns in series on the armature. Now, in this case the number of turns is a constant quantity, and since a gas-engine does not allow of much regulation of speed, owing to the governing appliances used, and also to the fact that the full power is not developed except above a certain critical speed, there remains but one method—viz., to alter the field strength.

From the description given the apparatus appears to be a private lighting plant, and in such cases the shunt regulator, if such is provided, will not allow of any such reduction in pressure as the occasion demands. To charge 20 cells in series will need from 50 to 60 volts, and to get this pressure under the conditions may be done in various ways. A large additional resistance inserted in the shunt circuit would (if the magnets are ordinarily worked well round the saturation curve) meet the case. It could be a water resistance, or, better still, a few yards of iron wire wrapped round a board and immersed in a tub of water.

Another way would be to excite the machine separately from the main battery of cells or a portion of them through an adjustable resistance, made as before described, and adjusted until the field was sufficiently excited to cause the machine to generate the required voltage. This latter will probably be the most economical procedure, but any method will necessarily be wasteful, however, if (as the query leads one to suppose) the affair is only temorary, this will not matter so much. It might even be done by charging at 100 volts through an iron-wire resistance, but this would be most extravagant. Of course, the querist must remember that when the shunt is adjusted for the proper voltage for switching in, it will require strengthening until the amperes passing through the cells are correct, these depending on the type, number, and size of plates.—A. B. F.

Answer to No. 383 (*awarded* 5*s*).—From the fact that when the battery of 53 cells are fully charged the voltage would rise from 106 volts before charging to 132·5—that is, 2·5 volts per cell—I conclude from the question that "A. R." does not want the voltage of his dynamo to rise above this amount, or say 145 volts at the most, which would be the case if the 20 new cells were connected up in series with the battery. The best way to connect up the new ones for charging would be first of all to join them (the 20) in parallel by connecting all the positives together and all the negatives. Now, the voltage of the whole 20 when charged will be only that of one cell when charged, so that the new cells can now be put in to the main circuit to be charged up with the rest—that is to say, connect them up as if only a new cell were being put in. As the new cells would probably require a much longer charge than the old ones before being ready for working, and as it is not necessary to run on for the sake of the 20 new cells, the best way to join them to the main circuit for charging would be to connect them up to the first stop on the regulating switch (*charging* side), taking care that

Digitized by Google

the discharge switch is not on the *same* stop at the time of doing so.

For the sake of simplicity, assume that the cable which comes to the first stop is joined to the positive end of a cell—in this case, the first cell. Then by disconnecting this cable from the positive end of the cell and joining it to the combined positive ends of the 20 new cells, also joining the combined negatives to the positive of the cell just disconnected, the 20 new cells will now be ready for charging. The advantage of joining the new cells to the first stop, as before mentioned, is that at the end of the day's charge these new cells can be cut out of circuit by means of the regulating switch without being discharged with the others. Of course, after two or three charges it will be found that the new cells will be ready for working; then they can be disconnected from the main circuit and joined up separately as required.—P. H.

NEW COMPANIES.

The following new companies have been registered during the past fortnight:

South American Syndicate, Limited.—Capital, £1,500. Object: to acquire real or personal property in South America or elsewhere, to acquire and operate any systems of tramways in South America, and to carry on the business of an electric light company, electricians, mechanical engineers, bankers, financiers, etc.

Tadcaster Electricity Company, Limited.—Capital, £6,000. Object: to adopt an agreement with Messrs. J. H. Ingleby, J. Bromett, and William Addinell, to establish stations and works, and to generate, purchase, and distribute electrical energy for the purposes of light, heat, motive power, and otherwise.

A. G. Beaver and Co., Limited.—Capital, £6,000. Object: to acquire the business carried on by W. E. Sotheby, at 151 to 157, Wardour-street, W., as A. G. Beaver and Co., to generate, produce, store, accumulate, and distribute electricity, and to carry on the business of electricians, mechanical engineers, manufacturers of electrical apparatus, metals, insulators, conductors, phonographs, bells, and other articles.

Hiram Maxim Lamp Company, Limited.—Capital, £70,000. Object: to adopt an agreement with C. M. Downie to carry on the business of electricians, mechanical engineers, producers and suppliers of electricity for the purposes of light, heat, or power, and manufacturers of and dealers in all apparatus and things required for and capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity, and for the purposes of the company to erect and maintain any shops, stores, warehouses, or other conveniences.

Inverted Incandescent Lamp Syndicate, Limited.—Capital, £12,500. Object: to adopt agreements with the Sunlight and Safety Company, Limited, and to carry on the business of lamp, burner, and fittings manufacturers, makers of appliances for increasing illuminating power, gas manufacturers, electricians, suppliers of gas and electricity, manufacturers of electrical accessories, etc.

Auto Carriage Company, Limited.—Capital, £20,000. Object: to adopt an agreement with Messrs. L. Ruef and F. Lane, and to carry on the business of manufacturers, hirers, and letters to hire of motors, motorcars, cycles, bicycles, tricycles, and mechanically-propelled vehicles and carriages for use on roads, railways, tramways, etc.

Magnus Volk, Limited.—Capital, £10,000. Object: to acquire, undertake, and work the electrical tramways on the beach in the borough of Brighton, east of the west entrance of the aquarium, now worked by Magnus Volk under the sanction of the Brighton Town Council, and any additions to and extensions of the said tramways, to carry on the business of tramway proprietors, electrical and general engineers, etc., and to adopt an agreement with Magnus Volk.

B. Thompson and Co., Limited.—Capital, £3,000. Object: to acquire and carry on the business carried on at Frome, Somerset, by B. Thompson, of mechanical, electrical, ventilating and general engineers, machinists, etc.

Kington Ironfoundry, Limited.—Capital, £10 000. Object: to carry on the business of ironfounders, machinery and implement makers, suppliers of electricity for light, heat, motive power, or otherwise, mechanical, electrical engineers, etc.

T. C. Welding and Co., Limited.—Capital, £1,000. Object: to acquire and carry on the business of Messrs. T. C. Welding and Co., of Liverpool, manufacturers of and dealers in electric fittings, etc.

Motor Trust, Limited.—Capital, £3 000. Object: to adopt an agreement and to carry on the business of Messrs. G. F. Milnes and Co., Limited, as manufacturers of and dealers in motors and other carriages, boats and launches, cycle builders, carpenters, electricians, mechanical engineers, machinists, etc

Daimler Wagon Company.—Capital, £100. Object: to acquire any licenses, patents, and the like, and to carry on the business of manufacturers of and dealers in all kinds of vehicles (whether worked by animal traction or by steam, oil, electricity, or other mechanical power), etc.

HULL ELECTRICITY ACCOUNTS.

From the accounts of the Hull Corporation electricity department just issued, it appears that the total expenditure on capital account to March 31, 1901, amounts to £169,979. Abstracts of the revenue account and general balance-sheet are given herewith:

Dr. Revenue Account.	£	s.	d.
Generation of electricity: coal, or other fuel	6,080	2	5
Oil, waste, water, and engine-room stores	545	14	6
Wages	2,499	19	2
Repairs and maintenance of buildings and plant	681	19	6
	9,807	15	7
Distribution: wages to linesmen, etc., £597. 16s.; repairs, maintenance, etc., of mains, £317. 5s. 8d.; repairs, maintenance, etc., of transformers, etc., £74. 19s. 11d.	989	1	7
Rents, rates, and taxes	1,220	6	9
Management expenses	1,592	13	2
Special charges	125	6	8
	13,736	3	9
Balance carried to net revenue account	10,840	19	9
	£24,577	3	6

Cr.	£	s.	d.
Sale of current per meter at 5d., 5½d. and 2½d. for lighting, and 2½d. per B.T.U. for motors	23,713	7	2
Rental of meters and other apparatus	769	8	4
Service connections, testing installations) etc.	61	8	0
Premium improver	30	0	0
Deposits (forfeited)	3	0	0
	£24,577	3	6

Balance-Sheet.

	£188,332	14	9

LEGAL INTELLIGENCE.

LIVERPOOL MORTGAGE INSURANCE COMPANY v. BRITISH ELECTRIC WORKS COMPANY.

In the Chancery Division of the High Court on Saturday Mr. Justice Cozens-Hardy heard an action brought by the Liverpool Mortgage Insurance Company against the British Electric Works Company, Limited, on a motion for judgment. It appeared that the action was brought by the trustee of a debenture trust deed, suing on behalf of himself and all other debenture holders in the company, which is a large Birmingham concern. The debentures had become enforceable by reason of the company having passed a resolution for the voluntary winding-up of the company and having failed to keep up the value of its cash in hand, book debts, and stock-in-trade to £30,000. The company, counsel stated, could not go on unless further funds were procured. Shortly after the action was commenced Mr. Justice Farwell appointed a receiver and manager, and no defence had been put in.

His **Lordship** said he was surprised that the company did not appear, and held that the plaintiffs were entitled to the order asked for. He accordingly granted the usual debenture holders' decree.

Mr. Eve, K.C., for the plaintiff, then said he had taken out a summons asking the Court's sanction to a conditional contract which had been entered into for the sale of the company's property to Vickers, Sons, and Maxim. The price to be paid was £60,000, and the purchasers undertook certain liabilities to the amount of £6,000. They acquired, amongst other things, the book debts and the cash. The summons also asked for payment of a commission of 2 per cent. to the late managing director of the company, who had negotiated the sale.

A liquidator of the company stated that at the meeting at which the voluntary winding-up was resolved on two liquidators were appointed, and they, although perfectly friendly, were unable to agree upon solicitors who should act for them. A

Digitized by Google

meeting of shareholders had been called in Liverpool for the following Wednesday, and if the summons stood over no doubt counsel would be instructed.

Mr. Eve said he was anxious that the summons should be speedily heard, as to keep the works going it was necessary to tender for large Government orders. The purchase would be completed one month after the sanction of the Court to the contract, or, at the latest, by July 31.

Mr. Justice Cozens-Hardy adjourned the summons till to-day (Friday) and continued the appointment till August 10 of the receiver and manager.

BICKNELL v. KALGOORLIE ELECTRIC POWER AND LIGHTING CORPORATION.

The case of Bicknell *v.* the Kalgoorlie Electric Power and Lighting Corporation has been heard before Mr. Justice Grantham and a special jury in the King's Bench Division of the High Court. The action was brought for the rectification of the defendant corporation's register of shareholders by removing plaintiff's name therefrom as the holder of 850 £1 shares, on the ground of alleged misrepresentation in the prospectus. Defendants denied misrepresentation, and counter-claimed for money alleged to be due in respect of calls.

Plaintiff's case was that certain important passages in the prospectus were untrue, particularly that to the effect that a valuable site for the installation of machinery and plant for power and electric lighting had been secured. It afterwards transpired, as alleged, that the only document the company could show was that they had 'secured a valuable right," and that was not granted until March, 1900, six months after plaintiff received the prospectus and bought the shares. It was said further by defendants that the Great Boulder Perseverance Gold Mining Company and the Great Boulder Main Reef had promised co operation, but it was found, according to the plaintiff's case, that they had, on the contrary, refused to co-operate. As a matter of fact, all that the companies in the district said was that if the defendant company could supply them with power at least 20 per cent. cheaper than was done at that time, and do so within a period of 18 months, they would give their support.

In the result, however, the jury found that the statements in the prospectus were true, and judgment was entered for the defendant company on the claim and counter-claim, with costs, application for a stay of execution being refused.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Taunton.—The Corporation invite tenders for free wiring. Tenders by July 1.

Manchester.—The Tramways Committee invite tenders for the supply of tramway rail bonds. Tenders by July 1. Details in our advertisement columns.

Kirkcaldy.—The Corporation invite tenders for feeders, mains, and roadwork and arc lamps. Tenders by July 20. Details in our advertisement columns.

Southwark.—The Electric Light Committee invite tenders for two additional panels to their main switchboard. Tenders by July 10. Details in our advertisement columns.

Amsterdam.—The Corporation invite tenders for tramcars for electric traction with overhead wire (perhaps 140). Tenders by Sept. 2. Details in our advertisement columns.

Dudley.—The Electric Light and Tramways Committee invite tenders for the supply and erection of a steam engine and dynamo. Tenders by July 6. Details in our advertisement columns.

Stepney.—The Electrical Committee invite tenders for steam and other pipework and paper-insulated cables, earthenware conduits, etc. Tenders by July 4. Details in our advertisement columns.

Poplar.—The Electricity Committee invite tenders for the supply of condensing plant, boiler feed pump, and steam and water piping, etc. Tenders by July 1. Details in our advertisement columns.

Bradford.—The Corporation invite tenders for electric motors (enclosed type), of 4½ h.p., 7 h.p., and 10 h.p., for a period of 12 months commencing Nov. 1, 1901. Tenders by July 4. Details in our advertisement columns.

Poplar.—The Electricity Committee invite tenders for the supply of multiple-core lead-covered feeder and network cable and accessories for mains extensions. Tenders by July 2. Particulars in our advertisement columns.

Madrid.—The Public Works Department of the Department of Agriculture, Madrid, invite tenders for the construction and working for 60 years of an electric tramway from Santiario de la Yedra to Baiza. Tenders by July 26. Particulars at that office.

Pontypridd.—Tenders are invited by the Guardians for the lighting of the union workhouse, infirmary, and other buildings in connection therewith by electricity. Tenders must be received by Mr. William Spickett, clerk, Union Offices, Pontypridd, on or before July 23.

Glasgow.—The Corporation invite tenders for the supply of concentric and single main cables, insulated with paper or fibre impregnated with oil, bitumen, or other substance impervious to moisture, or with vulcanised bitumen. Tenders by July 9. Details in our advertisement columns.

Cleckheaton.—The Council invite tenders for Lancashire boilers, economiser, jet condenser, feed pumps, suction pumps, Meldrum's destructor furnaces, balancers and boosters, accumulators, cables, switchboards, and travelling crane. Tenders by July 6. Details in our advertisement columns.

Brighton.—The Town Council invite tenders for the supply and fixing of all the wiring and fittings necessary for the electric lighting of the new floral hall of the market. Specifications, etc., may be obtained at the office of the borough engineer and surveyor, Mr. Francis J. C. May, M.I.C.E. Tenders by July 26.

Manchester.—Tenders are invited by the Electricity Committee for the supply of the following stores during 12 months ending June 30, 1902—viz: brass and iron castings, coal slack, cement, cotton waste, flags, incandescent lamps, meters, oils, timber, etc. Particulars, etc., may be obtained from Mr. F. E. Hughes, secretary, Electricity Department. Tenders by July 2.

Birkenhead.—Tenders are invited by the Corporation for the construction, supply, and delivery of 15 electric tramcar bodies, complete electrical equipments for 15 cars, and trucks and trolleys complete for 15 cars. Specifications, etc., may be obtained on application to Mr. Arthur R. Fearnley, tramways manager, Sessions House, Brandon street, Birkenhead. Tenders by July 16.

Rio de Janeiro.—Tenders are invited by the Brazilian Government for the supply of electrical machinery for the hoisting and transporting of locomotives at the Engenho de Dentro Works. Such particulars as have been received may be examined on personal application at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 5 p.m. Tenders by July 8.

Manchester.—The Tramways Committee invite tenders for (a) 5 000 cast-iron bases; (b) 5.000 pairs of cast-iron collars; (c) 5,000 cast-iron finials; (d) 5,100 cast-iron plates; and (e) 400 rosettes (including clevises and lewis bolts). Specifications, etc., may be obtained on application to Mr. J. M. McElroy, general manager. Tramways Department, 55, Piccadilly, Manchester. Tenders by July 8.

London, N.E.—Tenders are invited for the erection and construction of mechanical coaling apparatus for the municipal electricity works, for the Electric Lighting Committee of the metropolitan borough of Hackney. Specification, etc., may be obtained at the offices of Mr. Robert Hammond, M.I.C.E., consulting engineer to the Corporation, 64, Victoria-street, Westminster, London, S.W., on payment of £1. 1s. Tenders by 4 p.m. on July 4.

London, S.E.—The Borough Council invite tenders for the supply of electricity meters, demand indicators, and main fuses. Specifications, etc., can be obtained at the Town Hall, Spa-road, Bermondsey, on payment of a fee of £3. 3s., which will be returned on receipt of a bona fide tender. The specification may also be inspected (but not obtained) at the offices of the engineers, Kincaid, Waller, and Manville, 29, Great George-street, Westminster. Tenders by noon on July 1.

Mansfield.—The Corporation invite tenders for the supply and erection of—boiler-house plant: three Lancashire boilers, mechanical stokers, steam pumps, economiser, and motor; engine-house plant: three 200-kw. high-speed steam generators, motor transformer, balancing motor transformer, and accessories; Korting condensers and electric pumps, switchboard and instruments, accumulators, overhead travelling crane, electricity supply mains; public lighting: arc lamps, posts, and accessories; meters, and workshop equipment. Tenders by July 12. Details in our advertisement columns.

RESULTS OF TENDERS.

Stirling.—The Lighting Committee have accepted the tender of Messrs. Babcock and Wilcox, for the supply of steam-pipes, at £823.

Dundee.—The Council have accepted the tender of Messrs. Lowdon Bros., Dundee, for the overhead equipment in Seagate, at £2,010.

Hoylake.—The Electric Lighting Committee have accepted the tender of Brewer and Brunt, Hoylake, for the wiring of premises under the proposed system of deferred payments.

Hornsey.—The Council have accepted the tender of Braid, Pater, and Co., at £13,777, for the erection of the new electric lighting station. There were 11 tenders, the highest being £16,941.

Swansea.—The County Council have accepted the tender of the National Electric Wiring Company, Limited, 20, Wind-street, at £330, for wiring Guildhall and offices for purposes of electric lighting.

Thorpe (Norwich).—The Norfolk County Council have accepted the tender of N. C. Mann and Co., Redwell-street, at £4,000, for an installation of the electric lighting at the county lunatic asylum at Thorpe.

Poplar.—The Borough Council have accepted the tender of the Hart Accumulator Company, Limited, for the supply of a new storage battery, at £1,200, with an annual payment of £90 for five years in respect of maintenance.

Rochdale.—The Corporation have received tenders for six specimen electric tramcars from the British Thomson-Houston Company, 83, Cannon-street, E.C., and Messrs. Dick, Kerr, and Co., Prudential Buildings, 78, King-street, Manchester,

Digitized by Google

Walsall.—The Town Council have accepted the tender of Thomas Parker, Limited, Wolverhampton, for supplying and erecting the new transformer required for the Freer-street sub-station, at £780, and for supplying a spare armature for such transformer at £226.

Whitehaven.—The Town Council have accepted the following tenders: British Thomson-Houston Company, Limited, supply of new switchboard at the electric lighting station; H. Kitchin, erection of a testing-box at the corner of Lowther-street and King-street; Electric Power Storage Company, supply of six storage cells.

Swansea.—The Electric Lighting and Tramways Committee recommend that the tender of the International Electric Company, Liege, at £1,470, be accepted subject to the engineer's approval of the switchboard they propose to supply and to satisfactory assurance being given that portions of the machinery necessary for replacement would be readily obtainable.

BUSINESS NOTES.

TRACTION.

Dundee.—The Seagate tramways have been extended to Peep-o'-Day-lane.

Chester.—The opposition to the Corporation Tramways Bill has been withdrawn.

Leeds.—A start has now been made with the electric equipment of the Wortley tram route.

Cape Electric Tramways.—The directors of this Company have declared an interim dividend of 6 per cent.

Paddington.—The Borough Council intend to petition against the Middlesex light railway scheme in Parliament.

Grimsby.—It is expected that the electric trams between Grimsby and Cleethorpes will be running in a day or two.

Baker-street and Waterloo Railway.—This company have called up a further £2 per share, making the shares £6 paid.

Brighton.—The Corporation have decided to order five additional tramcars from the British Westinghouse Company, Limited.

Hornsey.—The District Council have decided to present a petition against the Middlesex light railways scheme in Parliament.

Southend.—The electric tramcars have been tested over the whole of the lines, and the Board of Trade inspection will take place shortly.

Sunderland.—It is expected that at the close of the current year the profits on the working of the electric tramways will be between £12,000 and £15,000.

Cardiff.—It is stated that an agreement between the Corporation and the tramways company has practically been arrived at as to the measurement of the lines.

Personal.—Mr. J. C. Whiteley, late of Halifax, has been appointed chief assistant engineer to Mr. H. N. Thomas, the electrical engineer to the Corporation of Huddersfield.

Edinburgh.—The Mound and Tollcross Corporation electric tramway route will be opened for traffic in about three weeks. The Portobello route, on the other hand, is not likely to be opened till the autumn.

Perth.—The Town Council in committee have agreed to offer the Perth and District Tramway Company £20,000 for the tramway system in Perth, with a view to equipping the same for electric traction.

Birkdale.—The Bill promoted by the Urban District Council to authorize the construction and working of electric tramways in the township has passed the House of Lords Committee presided over by Lord Harris.

Isle of Thanet Tramways.—Major Pringle has held an enquiry on behalf of the Board of Trade into the causes of various accidents on this system, which, it is contended, have affected and may in future affect public safety.

Blackpool.—The Tramway Committee have decided to alter the position of the pillars along the centre of Lytham-road to the side of the roadway. The line from Talbot-square up the New-road to the cemetery is to be proceeded with.

Black Country Tramways.—It is reported that the British Electric Traction Company have intentions of constructing a line from Dudley through Rowley to Blackheath. The Rowley Regis District Council have decided not to join the scheme.

The Liverpool Accident.—Mr. A. P. Trotter, Board of Trade inspector, has now issued his report on the trolley wire accident on the Liverpool electric tramway system on Feb. 4 last, the main points of which have already been given in a previous issue of this journal.

Gravesend.—The National Electric Tramway Company have notified their intention to apply to the Board of Trade for consent to transfer the tramways order to a new company—the Gravesend and Northfleet Electric Tramway Company—in consideration of the sum of £16,664.

Halifax.—Good progress is being made with the tramway line to Hebden Bridge. The lines have now been laid nearly to Mytholmroyd, and the Board of Trade have been asked to send an inspector, with a view to the extension from Luddenden Foot to Brearley being opened at once for traffic.

Sedgley.—The British Electric Traction Company have commenced work on the new tramway line, which will bring about a connecting link between the Wolverhampton borough boundary and Sedgley. The whole track which is 2½ miles in length, will probably be finished within three months.

Oldham.—The Park road, Glodwick-road, and Lees-road sections of the Corporation tramways undertakings were formally declared open on Saturday. These lines are a part of the scheme for the construction of 25 miles of electric tramways within the borough, and the portions opened are 2¾ miles in length.

Swansea.—The Swansea and district light railways order as submitted to the Board of Trade for confirmation authorises the construction of new lines from Sketty to Port Tennant, the extension of the present tramways to Cockett and to Midland-terrace, Morriston, and the laying of extra lines in the town itself.

Private Bills.—In the House of Lords the Worcester Tramways Bill has been read a third time, and the London County Council (Tramways and Street Widenings) and the Metropolitan Railway Bills a second time. In the Commons the Manchester and Liverpool Electric Express Railway Bill has been read a second time.

Electric Tramways and Magnetic Observatories.—A special committee appointed by the Government of Bengal to consider this matter in Calcutta, have expressed "their inability to suggest any rule, or rules, which will protect magnetic observatories from disturbance where the overhead trolley system of electric traction is used."

London County Council Tramways.—The London County Council on Tuesday voted over £2 000,000 for tramways and street improvements. The expenditure of this sum, of course, is dependent on the sanction of Parliament in the session of 1902. A list of the proposed routes and improvements was given in our last issue.

Richmond.—It is stated that an arrangement has been made with the London United Tramways Company that the agreement between them and the Richmond Town Council shall not be prejudiced by the decision of the Parliamentary Committee in regard to the company's Extensions Bill, and that it shall be the basis of any new Bill they may promote.

Wolverhampton.—It is reported that the Lorain Steel Company have sent a cablegram stating that they are willing to accept the contract to lay down their surface-contact system in connection with the Wolverhampton Corporation tramways with certain "verbal alterations." A meeting of the Tramways Committee will shortly be held to consider the point.

Manchester-Liverpool Monorail.—The Cheshire Lines Committee have further petitioned against the Manchester and Liverpool Electric Express Railway Bill. The Committee of Selection in the Commons has appointed Thursday, July 4, for a select committee to sit and proceed with the consideration of the Bill, as already sanctioned by the House of Lords.

Huddersfield.—A public meeting has passed a resolution favouring the application of the Corporation tramway men for payment on Sundays at the rate of time and-a-half, which the Tramways Committee have refused to grant. The Corporation have decided that the tramlines at Chapel-hill and Lockwood-road be doubled forthwith, at an estimated cost of £3,578.

Musselburgh.—On the question of the electric tramway between Musselburgh and Edinburgh, the Musselburgh Town Council have decided to lay a statement before the Board of Trade in regard to the position of affairs, and to point out that the order for the tramway had been promoted by the National Electric Traction Company, and that the Council were most desirous that the tramway should be made.

Paris-Berlin Motor Race.—General and widespread interest is being shown in the international motorcar race from Paris to Berlin, and a hearty reception awaits those who, being lucky enough to escape accident *en route*, arrive in Berlin in good time. It is asserted that the German Emperor himself will give a welcome on his own car to the first arrivals in the German capital. England is represented in the race by a 50-h.p. Napier car.

West Cumberland Tramways Bill.—This Bill has complied with the Standing Orders of the House of Lords, and has been sent for second reading in the Upper Chamber. Petitions on behalf of the Cleator Moor Urban District Council, Whitehaven Hematite Iron and Steel Company, and the National Telephone Company, praying to be heard against the Bill when the committee stage be reached, have been deposited in the Private Bill Office of the House of Lords.

Folkestone.—The Corporation have sealed their agreement with Lord Radnor in connection with the proposed tramways. A resolution has also been adopted that if at any future time tramways are constructed outside the urban district of Folkestone to the boundary thereof, and there are tramways belonging to the Corporation inside the urban district to the boundary thereof at the same point, mutual running powers should be conceded upon terms to be agreed upon.

Preston.—The Tramways Committee have considered applications from the promoters of the Lytham Tramway Company and the Horwich and Preston Tramway Company asking the Corporation's approval of their respective applications to the Board of Trade for powers to construct and lay down tramways within the borough boundary. It was decided to recommend the Corporation to appear at the Board of Trade enquiries mainly with the object of protecting the interests of the borough and to obtain protective terms.

St. Marylebone.—The Tramways Committee are of opinion that the proposed West and South London Junction Railway is undesirable,

Digitized by Google

inasmuch as the St. Marylebone portion would duplicate the lines of the already sanctioned North-West London Railway in Edgware-road, and, furthermore, the promoters of the West and South London Junction Railway propose constructing a station in close proximity to the intended station of the North-West London Railway near Marble Arch, at which point there already exists serious congestion of traffic.

Salford-Manchester Tramways.—Referring to our previous note on the subject, it has now been officially stated that the provisional agreement between the Manchester and Salford Corporations as to the working of the new electric tramway service over certain lines passing through the two districts has fallen through. The Salford Corporation have, therefore, decided to run their own cars entirely within their own boundary, and not to continue their service into Manchester. It is said, however, that there are hopes of a settlement in the near future.

Bath.—At the last Town Council meeting a formal resolution was passed empowering the authority to give notice to purchase the present tramway system. This step is in accordance with the agreement of the authority with the promoters of the electric railway, by whom the cost of the purchase will be borne. Mr. George S. Crisford has been retained to value the undertaking. The Chairman of the Tramways Committee stated that the conduit system was impossible owing to the arches in the city. The Clerk said that under the agreement they were pledged to the overhead system.

Glasgow.—The conductors and drivers belonging to the Coplawhill and Langside depôts of the Corporation tramways are agitating for payment on the same principle of daily pay as was formerly done and with an increase thereon of 2s. per week: to reduce the hours of labour to nine hours per day, or as near to that as could be conveniently arranged; and to pay "time-and-half" rate of wages for Sunday labour instead of, as at present, only the ordinary rate. An electric car driver has been fined a guinea for reckless driving in Eglinton-street on 11th inst., and another driver 10s. 6d. for a similar offence.

Metropolitan District Railway Bill.—This Bill, promoted by the railway company to carry out an agreement entered into with a company formed but not yet registered, called "The Metropolitan District Supply Company," came before the Select Committee of the House of Commons presided over by Sir John Kennaway on Tuesday. Mr. Pember, K.C., for the promoters, stated they had already power to apply electric traction, but the impecunious position of the company disabled them from going into the market to obtain the necessary capital to electrically equip the railway. Mr. Perks, M.P., a large shareholder, had entered into an agreement with Mr. Yerkes, a wealthy American financier, with the result that on favourable terms they had agreed to find a million of capital, to take up shares and to become practically partners in the working of the railway. Opposition was offered by the Metropolitan Railway Company and by the London and North-Western, who have running powers over the railway. It was stated that the objection of the former company was that the District Company by their Bill would require them to work on the section of the line common to both companies by the Yerkes system. If the Yerkes system were adopted, it would bar out the adoption of the Ganz system through the whole of the inner circle. It was obvious that there could be only one system in the circle. The question was which was the best.

London United Tramway Extensions.—The Select Committee of the House of Commons which has been considering the London United Tramways Bill has passed the preamble so far as it relates to 15 out of the 22 miles of new line proposed. The extensions granted comprise the whole of the company's proposals with regard to the group of lines in Kingston, Surbiton, Malden, and Esher, and also the Dittons and Molesey line, including the connections over the Kingston and Hampton Court Bridges, together with the company's authorised Middlesex tramways. The committee also passed the company's proposed electric tramway between Kew Bridge and Richmond, and the connection with Surrey from Hammersmith Broadway over Hammersmith Bridge. The chief proposal which has been rejected was to construct a line from Richmond to Putney, which would eventually join with the proposed London County Council system at the county boundary. The decision of the committee not to grant a license for this section, therefore, will prevent a through communication being established at this point, and leave a space of a mile or more between the termini of the two systems. This is to be regretted, inasmuch as great inconvenience to passengers and considerable waste of time must necessarily result therefrom. Another point worthy of note is that the committee decided that the existing Board of Trade provision gave gas and water companies sufficient protection against possible electrolytic action on their mains. The Bill now stands reported for third reading.

London Underground Railways.—On Friday Mr. Charles Booth gave some important evidence before the Joint Parliamentary Committee appointed to enquire into the routes proposed in various London underground railway schemes promoted in this session. He wished, he said, to see a complete system of tube communication in the area around London devised so that what was done locally might be brought into harmony with the whole. People might remove from a congested district to a longer or shorter distance if they had free scope for their choice, and gradually London would be expanded. There should be a gradual expansion in every direction, and by cheap and uniform fares people should be carried to any distance, just as in New York a five-cent fare would carry a passenger any distance up to 10 miles. Tramways should be worked by electricity in connection with, and extension of, tube railways, and they should also cover the ground now occupied by omnibuses. Colonel Yorke, chief inspecting officer for railways under the Board of Trade, also gave evidence founded on knowledge of the conditions of working traffic on the Central London, City and Waterloo, and South London underground railways. He supported, in the interests of economy and simplicity, the fixing of a uniform fare for each system. He was afraid that an all-night service would not be possible, because an interval of a few hours must be left for examination of the line and the work of repairs. On Tuesday the committee were occupied with the speeches of counsel in support of the several undertakings proposed, at the conclusion of which the room was cleared and the committee deliberated in private. On the readmission of the public, the chairman said the committee considered they had heard enough evidence, but if owners, lessees, and occupiers wished to say anything on the question of damage and the law on the point they would hear counsel, but not evidence. The committee then adjourned till Tuesday next.

LIGHTING AND GENERAL.

Yorkshire Electric Power Bill.—This Bill has been read a third time in the House of Commons.

Notting Hill Electric Lighting Bill.—This Bill has been read a second time in the House of Commons.

Pontypool.—The Guardians are investigating the question of lighting the workhouse with electricity.

Swansea.—Mr. J. H. Cawthra, electrical engineer to the Corporation, resigned his position on Monday.

Workington.—The Workington Electric Lighting Bill has been ordered to be reported for the second reading.

China.—It is said that a contract for the lighting of Pekin by electricity has been obtained by a German firm.

Bath.—An enquiry will be held shortly into an application to borrow £4,000 for the purposes of electric lighting.

Society of Arts.—Sir Frederick Bramwell has been elected to the presidency of the Society of Arts for the coming year.

Bedford.—A further sum of £3,000 is to be borrowed for electric lighting purposes at £3. 10s. per cent. per annum interest.

Beckenham.—Mr. M. K. North has held an enquiry into the application of the Council to borrow £20,000 for electric light extensions.

Glasgow.—The Corporation have decided to apply for a provisional order to supply electrical energy within the burgh of Kinning Park.

Heylake.—The contracts for the lighting of the town hall by electricity have been sanctioned by the Council, and the work will shortly be taken in hand.

Sligo.—Mr. Enright has advised the Corporation to summon a special meeting to give him authority to apply for an electric lighting provisional order.

Elland.—The report on the proposed electric lighting presented by Mr. Emmott, electrical engineer, of Halifax, is being circulated as private and confidential, and appears to be received favourably.

Factory Act.—Mr. Strachey, M.P. has consented to propose a clause in the Committee on the Factory Bill for the purpose of bringing Crown post offices under the operation of the Factory Acts.

Tadcaster.—The Guardians have granted sanction to the Tadcaster Electricity Company, Limited, to apply for a provisional order in pursuance of Section 4 of the Electric Lighting Act, 1882.

Sandgate.—The Council are urging the Hythe and Sandgate Electric Company to state definitely what they intended to do with regard to supplying Sandgate, as they have a number of applications.

Croydon.—Current for motive power is now to be supplied on the maximum-demand system. Sevenpence will be charged per unit for the first hour's average demand, and 1d. per unit for the remainder of the supply.

Falkirk.—A deputation of the Town Council is to visit Ayr, Edinburgh, Leith, and other places for the purpose of gaining information in regard to the working of the Council's electric lighting provisional order.

Electric Lighting in Wales.—The Bill to confirm provisional orders for electric lighting, which has passed the Examiner, and was reported for second reading in the Commons, contained provisions for Aberavon, Mountain Ash, Neath (rural), and Pontypridd.

Hornsey.—The Telephone Company having informed the Council that the telephone service would be resumed if the Council would allow a single pole to be erected at the corner of Hampstead-lane, the Council decided last week not to offer any opposition to this being done.

Institution of Junior Engineers.—The secretary (Mr. Walter T. Dunn) desires us to announce that the address of the institution on and after July 1 will be 39, Victoria-street, Westminster, rooms having been taken there on the first floor for offices, reading-room, library, etc.

Aberdeen Harbour Board.—At the last meeting of the Docks and Pilotage Committee of the Harbour Board the engineer reported that the electric lamps on the quay had now been fully equipped, and it was resolved to pay Mr. Bell, the electrical engineer, £50 for his services.

Digitized by Google

Dungannon.—The Bill to confirm an electric lighting provisional order to authorise the Urban District Council of Dungannon to supply electricity within the limits of their area has been reported for second reading.

Ardsley.—Application is to be made for an electric lighting provisional order authorising the Urban District Council of Ardsley East and West to supply electricity for public and private purposes within their district.

Simla.—Mr. Meares's scheme for the establishment of works for the electric lighting of Simla is estimated to cost approximately Rs 9,71,275. This figure includes the pumping plant and the cost of house wiring at Rs.30 per light.—*Indian Engineering.*

Aberdeen.—The kirk session of the East Parish Church are willing to pay £75 towards the cost of the electric lighting of that church on condition that the work of introducing the installation be commenced at once, and that the lighting arrangements be finished by the end of August.

Preston.—The Tramways Committee have been considering the question of the purchase of the electric supply company's undertaking for the supply of electric power, but it is stated that, owing to the prohibitive price asked by the company, the committee cannot recommend the Corporation to purchase.

Wireless Telegraphy.—The steamer "Tyrian" has been dispatched to establish the first Canadian station for wireless telegraphy at West Point, Anticosti. The "Tyrian" will also lay for the Government a cable 22 miles in length connecting Belle Isle with the Government line to Quebec.

Clyde Valley Electrical Power Bill.—The Examiner of Standing Orders has reported non-compliance in the case of the Clyde Valley Electrical Power Bill, so that it will have to come before the Standing Orders Committee of the House of Lords who will no doubt suspend the Standing Orders to allow the Bill to proceed.

Berkhampstead.—A special meeting was held last week to consider the advisability of obtaining a provisional order for the supply of electric light in the parish, but no decision was arrived at. The chairman stated that he was at St. Albans recently, and the mayor had publicly stated that they were going in for electric light there, and were not going to charge the ratepayers a penny for it.

Panteg.—The Rhondda Urban District Council having entered into an agreement with the South Wales Electric Power Company, by which the value of the unit would be the minimum of 2d instead of the maximum of 3d., the Panteg Urban District Council are taking steps to come to a similar agreement, as it is to be proposed to put down a third generating station there at some future period.

Bermondsey.—A tender was recently accepted by which the National Electric Wiring Company undertook to wire the town hall for £408. 14s. The account certified was £662. 15s. 8d., subject to a reduction of £59. 10s., leaving a total expenditure of £603. 5s. 8d. to be met, owing to a number of alterations for the making of which it is said the General Purposes Committee, and not the Electric Lighting Committee, were responsible.

St. Pancras.—The London County Council have decided to advance £50,000, part of a loan of £77 111, applied for for electricity purposes, on condition that it is taken up at once and repaid with interest at the rate of £3. 10s. per cent. per annum within 42 years, the Borough Council paying the costs of the loan. A previous resolution of the Council sanctioning the expenditure of £29,390. 5s. 6d. for additional feeding mains has been rescinded.

Brighton Telephones.—The Corporation have asked Mr. Bennett to prepare a map showing an extension of the Brighton telephone area to embrace Haywards Heath and Cuckfield and the adjoining rural districts, including Lindfield and Wivelsfield. They have also decided to ask the Postmaster General if he would be prepared to extend the Brighton telephone area so as to include the urban districts of Haywards Heath and Cuckfield and the adjacent rural area.

London County Council.—The Council have agreed to lend the Hampstead Borough Council £12,500 for purchase of a site for electric light station, and the Islington Borough Council £3 236 and the Stepney Borough Council £26 507 for electric light installations. On May 2, 1899, the Council gave permission to the National Telephone Company to lay three mains in the southern pathway of Bow Bridge, and we are informed that the company have abandoned their application.

Dundee.—At a telephone meeting of the sub committe appointed in connection with the proposed municipal telephones for Dundee on Tuesday, a letter was read from the National Telephone Company, protesting against any interference with the wayleaves of the company, and stating that the company had expended a capital of £95,000 in Dundee. Without dealing with the letter, it was resolved to send a deputation to Glasgow to make enquiries regarding the cost and working of the municipal telephone system there. It was stated that the income of the electricity department for May amounted to £601, which is £465 more than for the corresponding month a year ago.

Glasgow Telephones.—The Corporation have issued a preliminary list of their telephone subscribers, who are continually on the increase, the number at present being 739. The Corporation have over 5,000 lines on order, and claim that neither subscribers nor operators can overhear what is not intended for them. Another improvement is in the case of trunk calls from Post Office call boxes in other towns, only a simple trunk fee having to be paid without any terminal charge. Special agreements provide also for telephone messages for transmission over the public telegraphs, telephone messages to be forwarded as letters by post, and call for Post Office messengers for express delivery of letters or parcels.

Melton Mowbray.—The Lighting Committee of the Urban District Council having come to the conclusion to treat both the gas and the electric companies in a fair and impartial manner, decided that a tender should be sent in from each company for a period of three years. Subsequently the electric lighting company submitted two alternative schemes, at £325 and £335 per annum. The tender from the gas company came to £334. 13s. 4d. per annum. The lowest tender has been accepted by six votes to two, and the Council as a whole will act as a committee to obtain specimens of lamps.

Blackpool.—According to the last report the revenue for the year amounted to £23,530. 18s. 10d., made up as follows: Private lighting, £14 658; tramway current, £3 120; public lighting, £5,656; sundries £96. The expenditure totalled £16,186, leaving a gross profit of £7 345, dealt with as follows: interest and sinking fund, £7,550, less deficiency supplied by general district rate, £205—total, £7,345. The units generated in the year to March, 1901, are 1 760 459 against 1 427 607 last year, being an increase of over 23 per cent. At March 31, 1901, there were 910 consumers and about 80 miles of electric lighting mains. Number of public arc lamps, 240; incandescent lamps, 290. The total electric lighting capital stood at £145,094 at March 31, and the sinking fund at £11 845.

Clifton.—Messrs. Rouch, Lambert, and Penny, of 6, St. Stephen-street, Bristol, have just completed an electric light installation in the parish church. On the centre main ceiling are placed two pendant fittings, with 10 25 c.p. lights on each, controlled by two switches to enable either the full power or half power to be used. The galleries are illuminated by 12 three-light pendants, suspended from the ceilings, and underneath the galleries are 23 single ceiling lights. All fittings to the ceilings are arranged so that the light may be raised and lowered as required. Fittings have also been placed in the vestries, lobbies, tower, organ pedals, and crypt. It is probable that two more of the Clifton churches will follow the example of the parish church.

Improved Electric Glow Lamp Co.—This Company, who have removed to 7, Great Newport-street, St. Martin's-lane, state that they have taken this step owing to their inability to renew the lease (now terminating) of their premises, and on account of the large increase of their business in street lighting and other departments which will make the concentration of their offices and works an advantage. The Company hope in the future to confine themselves exclusively to the trade, while continuing to make a speciality of their electric incandescent lamps as heretofore, and of street-lighting and all fittings and work in connection therewith. The firm promises in addition an extensive show of motors and other electrical accessories of all description. Several new lists will be issued shortly.

Fulham.—On Dec. 15 1897, the late Vestry entered into an agreement with the National Telephone Company, Limited, consenting to their laying under the streets ground wire and cables, inspection chambers etc., for the purpose of telephonic communication, the company paying to the Vestry a small rental for such permission. The company laid various pipes and tubes, and on July 30, 1900, the Vestry, in pursuance with provision contained in the agreement, served the company with notice to remove all wires and cables, etc., within 12 months. This notice has now been withdrawn and a fresh agreement entered into, the company undertaking to lay no additional wires, cables, appliances, etc., without entering into a new agreement, to be entirely separate from the agreement first mentioned.

Brierfield.—According to the *Nelson Chronicle*, it appears that the recent action of the Corporation of Colne will almost certainly lead to the total collapse of the Brierfield electrical scheme. It will be remembered that at the last meeting of the Brierfield Council, Mr. Cooper, the electrical engineer to the borough of Colne, was practically appointed electrical engineer to the urban district of Brierfield, and was instructed to proceed with the scheme of erecting an electrical supply station at Brierfield to cost £10,000. This arrangement was a capital one so far as Brierfield went, but it was a one-sided one in which Colne could rightly be expected to insist on having a say, as that authority employs Mr. Cooper at a large salary to carry out their own electrical enterprises to success. But the Colne Electrical Committee subsequently decided to take such steps as would withdraw the services of Mr. Cooper, their engineer from the service of Brierfield Council. This is a heavy blow to the Brierfield scheme, as very great expense will have to be incurred in order to fill the place which Mr. Cooper has been called upon to vacate.

Bray.—The town clerk having submitted a statement showing that, looked upon as a trading concern, the electric light works showed a loss on the year's trading to March 31, 1901, of £605. 2s. 9d., and the matter having been discussed at length, the Electric Light Committee concluded that, having regard to the fact that the Council had been selling electric current for less than the cost of production, a revision of charges should be made, and recommended to the Urban District Council on the 20th inst. that from July 1 prox. the price of current be increased 1d. per Board of Trade unit—viz., to 7d., reducing to 4½d. after 1½ hours' lighting at maximum demand. Further special concessions to larger consumers to be made at the following rates—viz: 2½ per cent. off all quarterly accounts of £5 and over; 5 per cent. off all accounts of £10 and over; 10 per cent. off all accounts of £25 and over, provided such accounts be paid within one month after being furnished. The consideration of matters *re* extensions, new plant, etc., was postponed. The Council thought it was inopportune

Digitized by Google

to increase the price of cursent, and the report was sent back to the committee.

London Gazette.—A receiving order has been made out in the estate of C. A. Church (trading as H. Conolly and Co.), 120, Kentish Town-road and 12, Hampstead-road, London, on debtor's petition. The first meeting in the estate of the above was held on June 27 at 11 a.m. at Bankruptcy-buildings, Carey-street, W.C. The public examination will take place on July 24 at 11 a.m. at Bankruptcy-buildings, Carey-street, W.C.—The estate of A. G. Inrig (trading as the Globe Electrical Company), 46, Whitepost-lane, Victoria Park, has been released from trusteeship.—A receiving order has been made out in the estate of A. Sharp, lodging at Lane Head, Rastrick, Brighouse, Yorks, on debtor's petition. The first meeting in the estate of the above will be held to-day at Official Receiver's Offices, Town Hall-chambers, Halifax. The public examination will take place on July 15 at 2 p m. at County Court House, Prescott-street, Halifax.—The last day for receiving proofs in the estate of J. Brown, lately residing at 278, High-street, West Sunderland, is July 6. Mr. J A. Longden, official receiver, 25, John-street, Sunderland, is trustee.—The final meeting of the Premier Electric Lamp Syndicate Limited (in liquidation), will be held at the offices of Messrs. Wade, Chalmers, and Co., chartered accountants, 5, Fenwick-street, Liverpool, on Aug. 13 at 2 30 p.m.

Telephone Trunk-Line Exchange.—The new chief trunk line exchange at Franzosischeestrasse, Berlin, for the exclusive inter-urban and international telephone communication was opened on June 21. The system now in use means a considerable step forward in the development of telephony in Germany, for while up to now all trunk lines to Berlin terminated there, and could not be brought into connection with each other, the new trunk-line exchange enables the combining of any trunk-line wires, thereby providing the means of allowing telephonic intercommunication between not less than 17,000 towns all over Germany. This reorganisation naturally required an enormous amount of new and reconstruction, and the whole of the work connected therewith was laid into the hands of Messrs. Mix and Genest, Limited, of Berlin. This trunk-line exchange has been specially designed by the said firm, and has had a preliminary trial at the trunk telephone exchange at Chemnitz where during the short time of its introduction it has shown such reliability and such decided acceleration of service that the General Post Office decided upon its adoption on a larger scale for Berlin, and has now also ordered the trunk-line exchange at Magdeburg and Halle to be fitted up after the same plan. It is claimed that now the German Telephone Department possesses the most up-to date trunk-line exchange in existence.

British Thomson-Houston Co.—In view of the statements that have appeared in the daily Press, and in answer to numerous enquiries in regard to the same, the British Thomson-Houston Company inform us that the facts as reported are substantially correct. As is well known, the British Thomson-Houston Company own the patent rights for Great Britain of the General Electric Company of New York, the Thomson-Houston, and other companies, and, whilst the General Electric Company of New York have always been interested to a certain extent in the British Thomson-Houston Company, they have now increased that interest, and purchased British Thomson-Houston stock formerly held on the Continent. This does not affect the holdings in this country, and, in fact, the purchase meets with the approval of the British shareholders. The works now being built at Rugby will be pushed to completion, so that the manufacture of apparatus for the English market and export will be commenced as soon as possible. The Board of the British Thomson-Houston Company will be joined by Mr. C. A. Coffin, president, and General Eugene Griffin, first vice-president of the General Electric Company of New York, thus giving the General Electric Company of New York three directors out of a total of 13, Mr. W. J. Clark, the manager of the foreign department of the General Electric Company, already being a member.

W. P. Hartley, Bermondsey.—About 500 gentlemen assembled on Tuesday afternoon to witness the opening by Mr. H. C. Cust, M.P., of an extensive jam and marmalade factory at Green-walk Bermondsey New-road, S.E. The factory contains over 1,500,000 cubic feet, divided into seven or eight departments, as the largest building allowed by the London County Council must not exceed 250,000 cubic feet. Mr. Hartley comes from Aintree, Liverpool, where he has similar works, with a report of not only allowing his workpeople to share in his profits, but also of caring for their sanitation and comfort. The buildings are airy and substantial, and labour-saving appliances and electric fans abound. Five electric lifts have been fitted by Messrs. R. Waygood and Co., Falmouth-road, South Dover-street. They are of one-ton capacity each, the motors being of 17 h.p. Two Schuckert motors, of 10 h.p. each, are used for driving boxmaking and other machines. The 17 electric fans were made by Messrs. Matthews and Yates, Limited, and they vary from 18in. to 30in. diameter, the motors being of ¼ h.p. to 1½ h.p. The whole is lighted by about 700 16-c.p. lamps and 26 Thomson-Houston arcs of the enclosed type. The generating plant consists of two horizontal slow-speed engines made by the Burnley Ironworks Company, driving, by means of ropes, two A35 Schuckert multipolar dynamos, each having an output of 69 kw. at 220 volts. Space is provided in the engine-room for additional plant when extensions become necessary. Three 30ft. by 7ft. 6in. Lancashire boilers, made by T. Bellies and Son, Hyde Junction, constructed to carry a pressure of 150lb., supply the steam. Great attention is given to smoke prevention and smoke consumption. Mechanical stokers of the latest design are fitted, intended to minimise the escape of smoke to the greatest possible extent. The fine chimney stack is 130ft. high, with an unusually large internal flue, the diameter being 8ft. from bottom to top, with an outside base of over 16ft. across. The main switchboard is of white marble, and contains two dynamo panels fitted with ammeter, voltmeter, double-pole main switch, single-pole main fuse, automatic cut-out and shunt resistance for each machine, one spare dynamo panel for future machine, and two circuit panels for the various lighting and power circuits. The circuits are provided with throw-over switches, enabling them to be fed by either dynamo as required. The wiring is carried out on the distribution system, each floor having its own distributing switch and fuse board. The wires are, for the most part, run in wood casing, but in the boiling-rooms and other portions where steam and acid vapours are present, they are protected by insulated conduits. In the latter portions the fittings and distributing board cases are of watertight pattern. Mr. R. J. Wallis Jones, M.I E.E., of Great George-street, Westminster, was the consulting engineer. Mr. Fielden was the engineer for the contractors for the work, Messrs. Simpson Bros., of Hapton, near Burnley.

Kensington.—The Council are supporting the action of the London County Council with regard to the Notting Hill Electric Lighting Bill, and will ask the insertion of a clause providing that the powers under the provisions of the Electric Lighting Act, 1888, and of the Notting Hill Electric Lighting Orders, 1889 and 1895, of purchasing the undertaking of the company should extend to any lands acquired or works constructed by the company under the powers of the present Bill as if such land formed part of the undertaking; and they are of opinion that this course should be adopted, and that, if necessary, a petition should be lodged against the Bill in order to secure that the clause referred to be inserted. The lighting engineer has reported that he has been in communication with the several electric lighting companies in the borough in connection with the arrangements to be made for the lighting of Kensington High-street, Kensington-road, Brompton-road, Holland Park-avenue and High-street, Notting Hill, with electric arc lamps, and has ascertained from them that there will be no difficulty in getting a supply for the lamps, except on the north side of Kensington High-street and Kensington-road, in the area of the Notting Hill Electric Lighting Company. It appears, however, that this company would not object to the necessary current being obtained from the Brompton and Kensington Electricity Supply Company, who would light the south side of the road, and that the latter company are willing to supply the lamps from their mains on the south side of the thoroughfare. The Council are communicating with the two companies with a view to the difficulty being satisfactorily arranged.

New Issue.—The Urban Electric Supply Company, Limited, incorporated with a share capital of £500,000, divided into 50,000 5 per cent. cumulative preference share of £5 each (£250,000) and 50,000 ordinary shares of £5 each (£250,000), of which 4,000 ordinary shares have already been subscribed for by, and alloted to, Edmundson's Electricity Corporation, Limited, are issuing 30,000 5 per cent. cumulative preference shares of £5 each and 30,000 ordinary shares of £5 each. A dividend of 5 per cent. on the preference shares and a minimum dividend of 5 per cent. on the ordinary shares has been guaranteed until Dec. 31, 1910, by Edmundson's Electricity Corporation, Limited. The directors are Messrs. Francis Edward Gripper, M.I.E.E. (managing director Edmundson's Electricity Corporation, Limited), Clifton Villa, St. Margaret's-on-Thames (chairman); Edmund Charrington, A.M.I.C.E., Mayfield, Chislehurst, engineer; Herbert Brent Grotrian, Hare-court, Temple, E.C., barrister-at-law; William Page (director of the Brompton and Kensington Electricity Supply Company, Limited), Rickmansworth; John Cuthbert Wigham (director Woolwich District Electric Light Company, Limited), Coanwood, Surbiton. Mr. F. Hastings Medhurst M.I.E.E. (F. H. Medhurst and Lloyd), 13, Victoria-street, Westminster, S.W., is the consulting electrical engineer. This company was formed in 1898 for the purpose of obtaining powers to work electric light and tramway undertakings in various places in England and Scotland. Powers have been acquired either by this company or by others acting under its control for electric lighting in Camborne and Redruth, Glossop, Twickenham, Hawick, Grantham, Berwick-on-Tweed, Bishop Auckland, Godalming, Newton Abbot, Stamford, Dartmouth, and Weybridge, and for 3½ miles of electric tramways in Camborne and Redruth, and a provisional order for the 4½ miles of tramways at Glossop has been granted by the Board of Trade with the sanction and support of the Corporation of Glossop, and only awaits the usual confirmation by Act of Parliament. The construction of the works will be undertaken by Edmundson's Electricity Corporation, Limited, which provides, *inter alia*, for their profit being fixed by the consulting engineer of the company, or in case of difference by arbitration. They also undertake the supervision and general management of the various works until Dec. 31, 1910. Mr. Medhurst recently inspected all the towns for which the company hold electric lighting and tramway provisional orders. Regarding Twickenham, Grantham, Berwick-on-Tweed, Newton Abbot, Stamford, and Weybridge, he states that there is certain to be a good demand for electrical energy for lighting purposes in each of these towns, and that in each of them the price at which consumers will obtain electric light will compare very favourably with the present rates for gas-lighting. At Dartmouth the Government is erecting a great naval training college, and he understands that this institution will require electricity for some 3,000 lights from the company's Dartmouth central station. At Godalming the Charterhouse School will require a considerable supply of current in the coming winter. Mr. Medhurst considers the terms of the contract between the

Digitized by Google

Urban Electric Supply Company, Limited, and Edmundson's Electricity Corporation, Limited, is in every respect most fair and reasonable, as all the shareholders of the Urban Electric Supply Company, Limited, are certain to receive 5 per cent. interest on their capital from the date of their subscriptions till the end of the year 1906. By the end of 1907 he estimates the capital expenditure will have increased to £650 000, and that the output and commercial results will be as follows: Net revenue, 1907—2,800,000 units at an average profit of 3d. (difference between 2½d., the cost of production, and 5½d., the price obtained), £35,000; 420,000 car miles at an average profit of 4d. (difference between 5½d. and 9½d.), £7,000—total, £42,000. He thinks the sum of £650,000 above mentioned might well be made up as follows, when the result would be: £150,000 debentures at 4 per cent. require £6,000; £200,000 5 per cent. preference shares require £10,000—total, £16,000; leaving for £300,000 ordinary shares, £26,000; which is equal to 8¾ per cent. In order to show the steady increase in net profit with every justifiable increase in capital expenditure, the following figures are given: Capital outlay in 1910, £1,000 000, made up as follows—£300,000 4 per cent. debentures, £350,000 5 per cent. preference shares, £350,000 ordinary shares. Net revenue, 1910: 5,800,000 units at an average profit of 3d. per unit, £72,500; 480,000 car miles at an average profit of 4d. per car mile, £8,000—total, £80 500; £300,000 4 per cent. debentures require £12,000; £350,000 5 per cent. preference shares require £17,500; 1½ per cent. depreciation requires £15,000—total, £44,500; leaving for 350,000 ordinary shares, say, £36,000 (which is equal to 10 per cent.). Full particulars will be found in another column.

PROVISIONAL PATENTS, 1901.

JUNE 17.

12329. Improvements in electric meters. Arthur O'Neill Fox, 46, Lincoln's-inn-fields, London. (Complete specification.)

12342. Improvements relating to electromagnetic winding mechanism for clocks. Theodor Schäffer, 11, Southampton-buildings, Chancery-lane, London.

12350. Improvements in revolving electric igniters. Anson Groves Ronan, 40, Chancery-lane, London.

JUNE 18.

12382. Improvements in portable electrically-driven drilling apparatus. George Frederick Campbell and Stanley Thomas Isherwood, 34, Castle-street, Liverpool.

12400. Trolley for electric cars. John Liddle, 154, St. Vincent-street, Glasgow. (Laclede Car Company, United States.) (Complete specification.)

12403. Improvements in bonding electric railway and tramway rail joints. John Stanley Holme, The Promenade, Egremont, *vid* Liverpool.

12408. Improvements in and relating to static rectifiers and other electrical apparatus for producing or maintaining continuous or unidirectional discharges. Thomas Burton Kinraide, 55, Chancery-lane, London. (Complete specification.)

12456. Improvements in or relating to trolleys for use in electric traction. John George Lister, 111, Hatton-garden, London.

12466. Improvements in apparatus for deriving continuous current from a source of alternating current. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktiengesellschaft, Germany.) (Complete specification.)

12468. Improvements in the manufacture and production of troughs or conduits specially intended for the reception of electric cables. Albert Harris Howard, 47, Lincoln's-inn-fields, London.

12469. An improved current transformer for telephones. Benoit Joseph Berthelon, 40, Chancery-lane, London.

JUNE 19.

12495. Seeing by electricity. Ludolph Fränckel and Richard Robert Harper, 5, South-grove, South Tottenham, London.

12502. Improvements in apparatus for deriving continuous current from a source of alternating current. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Actiengesellschaft, Germany. (Complete specification.)

12509. Improvements in apparatus for deriving continuous current from a source of alternating current. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Actiengesellschaft, Germany.) Complete specification.)

12514. Improvements in or connected with storage or secondary batteries. John Crisp Fuller and George Fuller, 33, Chancery-lane, London.

JUNE 20.

12551. Improvements in and relating to trolley pulleys for electric tramcars and the like. Robert Wylie, 96, Buchanan-street, Glasgow.

12562. Improvements in electric arc lamps. Crompton and Co., Limited, Arthur John Hodgson, and John William Ewart, The Arc Works, Chelmsford.

12587. Improvements in and relating to apparatus for lighting and heating by means of electric lamps. Richard Wade Boyd, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12607. Improvements in and relating to plates for electric batteries and methods for manufacturing the same. Edward Bennett Viles, 322, High Holborn, London.

12622. Improvements in electric instruments. Evershed and Vignoles, Limited, and Sydney Evershed, 1, Queen Victoria street, London.

JUNE 21.

12685. An improved method of registering electric currents. Samuel Jevons and Edward William Bonson, 77, Colmore-row, Birmingham.

12691. Improvements in electric cloth-cutting machines. Robert Edward Leve, 6 Bream's-buildings, Chancery-lane, London. (Complete specification.)

12720. Improvements in or connected with electric cables for three-phase alternating current. William Beedie Esson, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

12721. Improved machine for use in the manufacture of electric fuses or cartridges. Hans Tirmann and Hugo Tirmann, 111, Hatton-garden, London. (Complete specification.)

JUNE 22.

12730. Improvements in cleats, ceiling roses, cut-outs, and the like for electrical purposes. Charles Cartwright Metcalfe, 50, Oldfield-road, Sale, Cheshire. (Harry Cecil Blackwell, Russia.)

12739. Improvements in electrically-driven centrifugal and similar machines Gideon Pott and Robert Williamson, 62, St. Vincent-street, Glasgow.

12755. Improvements in electric meters. Joseph Matthews and William Davies, 77, Colmore-row, Birmingham.

12773. Apparatus for automatically regulating the tension of electric currents. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Moritz Lindner, Austria.) (Complete specification.)

12773. Improvements in wattmeters. José Batlle and José Bueno, 322, High Holborn, London. (Complete specification.)

12774. Improvements in cell switching devices for electric accumulator batteries. Max Gehre, 6, Lord-street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published on July 13.

1900.

5387. Apparatus for wireless telegraphy. Marconi.

11035. Electric apparatus for lifebuoys and lights to facilitate the rescue of persons from drowning and for other purposes. Binko.

11206. Electric switches and like apparatus for making and breaking electric circuits. Partridge and Elphinstone.

11283. Electric signalling apparatus. Warden-Stevens.

11727. Electric switches having intermittent or step-by-step motions. Kingsland.

11853. Flag or banner poles or for use in connection with arc lamps or for other like purposes. Grindrod.

15019. Recovery of tin and the simultaneous generation of electric energy. Gould.

15021. Manufacture of carbon electrodes for arc lamps. Alexandroff.

15363. Electro-deposition of metals upon articles of china, earthenware, and the like. George Cooke and Joseph Parr.

17765. Connecting the glow bodies of incandescent electric lamps to the leading-in wires. Scharf.

1901.

1994. Electrical meters. Fenny. (Allgemeine Elektricitäts-Gesellschaft.)

2009. Electric arc lamps. Fairburn-Hart. (General Electric Company.)

3002. Electrical insulators. Harloe.

3206. Equalising appliances for inner-connected polyphase currents. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

4868. Electric switches. Scott. (Date applied for under International Convention, Aug. 16, 1900.)

5596. Electrolysis of chlorides of metals of the alkalies and alkaline earths for the purpose of obtaining chlorine and apparatus therefor. Atkins.

6288. Coin-freed meters for gas or electricity. Smith and Smith.

6884. Protecting covers for steam-pipes, water-pipes, rods, chains, wire ropes, or electric wires for ship purposes. Hudson.

Digitized by Google

5134. Conduits for electric cables and the like. Hultman.

9384. Electric arc lamps Johnson and Esson.

10623. Telephone apparatus. Nicholson and New Phonopore Telephone Company, Limited.
